W. H. Gower, writing of exotic Ferns, uses Latin names only. "S. G." writing of British Ferns, in all cases uses the Latin names as well as the English. W. Goldring, writing of American trees, gives the American name as well as the Latin in part. In one case he uses the full Latin name, which tells me what he means; in the other, the Nettle tree or Hackberry, I have to refer to Gray's "Flora" to see what species of *Celtis* he alludes to; so nothing is gained in this case by the addition of two English names.

All the rest of the writers, including such well-known names as those of the Rev. Wolley Dod and Mr. J. Douglas, use Latin names only; so that we must conclude that some who at any rate would not like to be called narrow pedants do agree with me that for all but common well-known plants, names in a foreign tongue are more necessary and reasonable, because more convenient than English ones. I hope he will now acquit me of any other wish than that, by freeing the language, methods, and practice of botanists of all which is difficult, useless, or incorrect, to make it more attractive to gardeners, who can no more get on without the help of botanists than botanists can get on without their help. By the union of these two sciences the highest rank in both can alone be reached. Why, then, should an author who has done so much to popularise and advance horticulture as the editor of THE GARDEN seek to degrade it by scoffing at correct nomenclature?—H. J. ELWES, *Preston, Cirencester.*

— I am happy to see Mr. Elwes is no hater of English names, after all. To find him content with one is delightful! And actually to object to giving the Latin name to the pretty wild north-of-England *Viola*, though there are many others, is most hopeful. He evidently feels it is inconvenient for horticulturists and botanists like himself and for the trade to be bothered by a new English name. Later on he will, no doubt, begin to feel for the men, women, and children for whom, as well as for the trade or the specialist, flowers were made. This is the most important point omitted by all who oppose English names for garden plants. A professor of chemistry teaches specialists whose business it is to understand terms not commonly used. But anyone teaching the knowledge of plants and flowers should make himself clear to all, even to children. If people were all trained gardeners and distinguished amateurs like Mr. Wolley Dod,

the question need not be raised at all. It is not a question of class or education. Without any disrespect to the gentlemen named by Mr. Elwes, there are many persons no less distinguished in other ways—persons of the highest influence and best education—who regret and deplore what they call the barbarous learning of the gardeners. Indeed, it is often a theme for laughter. As a rule, the more educated and refined the person, the more likely is he to use simple English words, where it is possible to do so, for flowers. It is a delightful privilege of gardeners that they deal with the fairest things in Nature: it is their own great loss if they mar the lesson with a strange and, to many, impossible nomenclature. This has had possession of our gardens so long, that it will take long to change it, but changed it must be! Inconvenience may be caused to many, but this must not stop our efforts. The evil effects of the system in use are enormous. It has tended to make a beautiful and simple art, meant for all, the possession of a class.

The view taken by intelligent owners of gardens is fairly shown by the following letter received during the past week. It is from a lady familiar with garden plants both by their Latin and English names:—

TO THE EDITOR OF THE GARDEN.

SIR,—Some reference to this subject in a late number leads one who strongly feels the want of English names to ask why it is only in the case of botanical scientists that the wish should exist to impose their technicalities on the flower-loving public. The living things, objects, or substances that are classified in other branches of natural science, or, at any rate, those of them that affect our every-day lives, have their common English names accepted and undisputed by the learned, who specially profess the various branches of knowledge; but the botanist alone takes some other view, and decrees that plants and flowers shall not be represented by any words in our language. Is not the plain fact of anything being commonly known and used reason enough for our having a common name to know it by? Why are flowers and flowers only to be denied popular names such as are in use for every well-known beast, bird, fish, reptile, insect, and their limbs and parts, and every well-known or generally used chemical or metallic substance, and every other sort of thing for which it is judged necessary to have a scientific formula, or a name in Latin or Greek, or a middle of both? It is in reality only for international reference that the scientific names exist at all. If there were only one language and one written literature, and that were English, a Pansy would be a Pansy all the world over, and no one would dream of calling it *Viola tricolor* var. hort. Indeed, it is much to be doubted if the botanist himself would do so, if he possessed a human heart not entirely desiccated in his herbarium and were walking round a friend's garden one of these days of May. So that some of us who have a garden (or should one say a "hort?") venture to think we may leave the Latin names to their own purposes, and without blame talk of Primroses and Cowlips, and even accept such a new name for a new comer as may be well fitting to the plant and to our British mouths.—X.

Mr. Ruskin's opinion has been published long ago in THE GARDEN. He laughs the

whole thing to scorn, and shows how the "lingo" of which these names are composed is as impure as it is ugly. He takes a page of the *Botanical Magazine* and shows absurdities in it tenfold greater than Mr. Elwes points out in our despised English naming. The Latin names we must, however, keep for international use. For garden and cultivated plants a good short English name is more essential than a correct Latin one.

NEW ENGLISH NAMES.

Mr. Elwes, while accepting, as now appears, old and common English names, objects wholly to new ones! Latin names may be coined every day, but English names are to stop growing. This surely is not scientific, as we are told that language grows and decays. Any cottager might call a plant "Lipsmart" a hundred years ago, but I, who speak of flowers to many thousand persons every week, must not do so. It might bother the botanist in his researches to find a new English name! And the trade too—how very unkind to compel them to find English names for the plants they grow!

Well, I did not consider the trade or the gardeners much when beginning, unaided, the attacks on bedding-out. Many things were said that would not look pretty in print. But many see now that "bedding-out" was the greatest enemy the trade and gardeners ever had. So the day will come, I trust, when people will wonder at our present use of words, when children will learn to know plants by names as pretty as their flowers. The subject may be commended to some of our young men who, having had "all the chances," may be seeking useful work. The successful one must be gardener, botanist, poet, and English scholar in one. The right man will take the new Anglo-Saxon and other dictionaries, Miller, Ruskin, and all available aids up to the date of his start, and, keeping the best of all (including the good and beautiful Latin names like *Iris*), aim to give us a really simple code of English nomenclature that the English-speaking world could follow and add to.

All the difficulties of English nomenclature must be faced, and they will be got over in due time. There are a great many more English names than is supposed. If anybody looks over Miller's Dictionary, he will be surprised to find the number of pretty names to plants that he never knew were blessed with such. Many old colonial, American, and forgotten names belong to plants that we every day in gardens speak of by their botanical names. Nurserymen will have to publish full catalogues with English names. In my *GARDEN and Gardening Illustrated* I request everybody to use English names in all cases where possible, adding Latin names as an aid. But we are so much the slaves of the old Latin nomenclature, that I find my people every day using Latin names in cases where there are very good English names. No doubt many plants have no good English names, but

that is no reason why good ones should not be invented for them. I believe I shall yet get Mr. Elwes' help in the English christening of pretty plants. I was once like him, and fancied I enjoyed names such as *Aponogeton distachyon*!

By the way, a lady sent me this week a suggestion that the pretty little hardy *Tiarella* should be called Foam Flower. It is a beautiful plant with what might be well called "fine foliage" and very pretty *Spiræa*-like blossoms, which come so thick and white and airy, that the word "foam" may well be applied to a rich border of it. Now, this little plant has been in botanic gardens for many years, usually crouching behind a label. I believe that under its new name the Foam Flower, which, with due deference to Mr. Elwes and all opponents of English names, I now adopt for it, it will some day be in almost every English flower garden. There is no better thing in our gardens, and it is the most delightful plant I know for carpeting a dark or moist, or rocky or shady corner. I shall figure it and publish it with this English name.

As soon as Miller's Dictionary in its present form is exhausted, it is hoped that it will be published at a very low price, so as to enable all interested to have ready reference to such English names as we already possess.

The Americans will take English names for plants up in time, and perhaps some bright man among them may do the great work before us. This, in spite of our excellent friend Meahan, of Philadelphia, who, however, is a born botanist and happier reading a paper on "*a weeping tendency of certain stems of a fungus observed on the fin of a Gasterosteus (=stickleback)*" than going about a fair garden smelling the Roses! The very name of THE GARDEN should prevent Mr. Elwes from supposing we have any aspirations, or any desire even, to be a scientific journal in the narrow sense in which the abused word science is often and wrongly used by ordinary folk, and also by the botanist and botanical persons. But philosophers, who rise higher in thought and learning, tell us that all human knowledge is the same in kind, and that the labours of a peasant on his land, if carried out in due order after just observation of the seasons, may be as truly scientific in their way as those of a good astronomer, however they may differ in degree. We are, as Mr. Wilks lately said, only humble gardeners, but our calling is not less dignified, not less useful than any other, and it may in many ways be real science. As to its beauty and innocent healthfulness, all men are agreed. English names of plants, such as we seek, need not be any less "scientific" than Latin ones; certainly it might easily be more so than the (according to good scholars) polluted tongue botanists have hitherto given us.

An idea occurs to me as I close—it is, that if a few would help me, we need not wait to provide work for that bright and well-taught poet-gardener, who may have his own notions of amusing himself. I think Mr. Burbidge,

if he tried, could find names for the cultivated *Orebrids*—Lindley's "*Oreontoglots*," &c., will never do. I might try the hardy plants. Mr. Elwes might relent and help us with the Indian plants, and we should have the sympathy of men like Mr. Ruskin and Professor Earle. Mr. Ruskin's name "*Rockfoil*" for the *Saxifraga* is excellent, and should encourage us. All this might lead to the issue of a "*Garden Flora*" with English names printed below a good illustration of each plant or genus. Indeed, I think I had better begin soon by publishing in THE GARDEN the plants in their Natural Order, illustrating the families and typical species, such as our native mossy *Rockfoil* (*Saxifraga hypnoides*). W. R.

FLOWERS IN THE HOUSE.

Under this head we propose, during the present season of flowers, to notice things, from whatever department, that are pretty and useful for the house.

TUFTED PANSY LITTLE HARRY.—The richest of all the violet-purple Pansies. From Mr. Poë.

*

ORIENTAL POPPIES.—Sent by Mr. W. B. Hartland. Flowers splendid for colour, but the smell deadly.

*

THE AMETHYST HYACINTH (*Hyacinthus amethystinus*).—A unique colour amongst spring and early summer bulbs; a lovely hardy bulb, and coming in late.

*

HABRANTHUS FULGENS.—The brightest bit of colour to be had out of doors in the garden—a really splendid hardy plant which Mr. Poë flowers well. It is very uncommon.

*

ST. BRUNO'S LILY.—One of the loveliest of earliest summer flowers and good for cutting. With *Globe* flowers it makes a very satisfactory alpine meadow bouquet.—J.

*

IRIS CIENGALTI.—A beautiful dwarf *Iris*, very good in colour; nearer blue than any other of the broad-leaved kinds. Arranges well in water with the large white Iceland Poppy and sprays of *Whortleberry*.—J.

*

MUNSTEAD WHITE COLUMBINE.—What a beautiful flower for specimen glasses, so remarkably graceful. Large masses with white *Rockets*, *Oriental Poppies*, and *Chinese Pæonies* are now grand.—W. B. H.

*

SCARLET THORNS.—Mr. Hartland, writing from Cork, says: "I never saw the double scarlet Thorn and *Laburnum* flower with such luxuriance. You could not see a green leaf on the *Laburnum*."

*

WHITE ICELAND POPPY.—This is a large form, raised by Miss Davidson, and known at Munstead by her name. It is delicately crimped, petals lemon, green centre. A very striking and graceful flower.—W.

*

TUFTED PANSIES.—Very large and beautiful, from Mr. Hartland, of Cork. We admire *Lady Polworth*; *Rennie Donaldson*, purple striped eye; and *Countess of Kintore*, very striking. Mr. Hartland says: "No manure, but rich maiden loam and sea sand for soil."

*

COLUMBINES.—I send you some seedling *Columbines*. They do not require much atten-

tion, and delight in a heavy, rich soil. I also send you a few varieties of flowers cut from the herbaceous borders. From these we can now gather a great variety of cut flowers.—W. A. COOK.

*

VERONICA HULKEANA.—A long and graceful panicle of delicately lavender coloured flowers from Mr. Greenwood Pim, Dublin. A very pretty and elegant plant, and we shall be glad if Mr. Pim will tell us how it grows in Ireland.

*

NARCISSUS GRACILIS.—The latest and one of the most graceful of the coloured Daffodils; in colour quite unlike any other—a soft, mysterious, transparent-looking yellow. Very pretty in a slender glass with branchlets of yellow-green-leaved Oak and Oak Apples.—J.

*

BLUE CORNFLOWERS.—Autumn-sown plants, or rather summer self-sown, give these fine strong flowers that no spring-sown plants can ever show. The advantage of autumn-sowing, in the case of many hardy annuals, cannot be too strongly insisted on.—G. J.

*

MOUNTAIN CLEMATIS.—Sent from Ireland by Mr. Greenwood Pim. It would, perhaps, be a good sign if these plants were as common in Irish villages as in some parts of Wiltshire. Its use on houses is everywhere recognised, but why not plant it in other ways, against dead stumps, or even on branches over a bank? It came into the world before walls.

*

DOUBLE LILACS.—M. Lemoine, of Nancy, sends us charming double Lilacs—Michel Buchner, President Grévy, and Alphonse Lavallée. They are far prettier than we expected them to be. Their value with us can only be tested when they are planted out, but they are very promising; far better, indeed, than the worthless double Wistaria introduced some years ago.

*

ICELAND POPPIES.—Mr. Hartland writes on June 6: "We have Munstead white, yellow, and scarlet Iceland Poppies planted on the surface of a bed of pallidus præcox Daffodil in light soil, the Daffodil foliage being now quite gone, and now we have these beauties in full glory. They are very continuous and floriferous. The bees are delighted with such food."

*

FLOWERS FROM NORTH DERBYSHIRE.—The few bright days have produced a marvellous change in this district. The sunny sides of the rocks are bright, the Golden Rock Rose growing amidst the Wild Thyme. The dark coloured Crane's-bill (*Geranium phæum*) is rather interesting, and grows in the woods here.—GEORGE BOLAS.

*

IXIAS FROM READING.—I send you some *Ixias* and a spray of the rock Forget-me-not (*Omphalodes Lucilæ*). The *Ixias* are grown in a border outside a greenhouse, and have a glass coping over them in winter. The bed gets some little help from the pipes inside the house, so that nothing but the surface, if that, ever freezes. I wish you could see the *Marica cærulea* and catch its glorious blue.—A. C. BARTHOLOMEW.

*

RHODODENDRON EDGWORTHII.—The accompanying truss is cut from a plant given to me three years ago, when quite small, by Sir Joseph Hooker, who wished me to try how the Worthing climate suited this and certain other Himalayan species. It has never had the slightest protection, save such as afforded by a high perpen-

dicular face of rockwork with a northern aspect, which shelters from wind while it screens from sun. It grows in a border of common peat. I am not aware that the plant has ever previously flowered out of doors in England.—JAMES BATEMAN, *Home House, Worthing*.

*

ROSES FROM SOMERSET.—Mr. J. C. Clarke, Taunton, sends very fine Tea Roses from the open air, grown on a south wall—among them our old friend Souvenir d'un Ami, Safrano, Marie Van Houtte, Homer, the beautiful Mdme. Lambard, and Belle Lyonnaise. They are not large as yet, but very welcome; they are no novelty now; Roses have come at last. We saw many in the Sussex gardens, and hope the time of Roses will be long and good.

*

DOUBLE BUTTERCUP.—I have enclosed a few blooms of a double variety of the common bulbous Buttercup, thinking it may be of interest to you. It was found growing wild in a field near Leatherhead, in Surrey, about ten years ago, by a relation of mine, and since then cultivated by me as an herbaceous plant; it has proved very interesting to many people both horticultural and botanical.—C. ORCHARD.

*** A pretty double Buttercup.—ED.

*

HYBRID BARRENWORTS (*Epimedium*)—I have put in the box two or three leaves of hybrid *Epimediums*. I wonder these plants are not more grown for foliage. *Epimedium* was the first plant I ever tried my hand on at hybridising, thirty years ago! Some one said in THE GARDEN a week or two ago that *E. colchicum* was white. He is wrong. *E. macranthum* is tinged white; *E. colchicum* is bright yellow.—A. RAWSON, *Widernere*.

*

BLUE TIPPED PANSIES.—What a superb Pansy is Archie Grant! It is at present doing finely with me, the blooms large, of fine form and substance, and of a deep indigo blue. I would send you flowers, but I know too well how blues suffer in the London light, and those of blue tints, which are so lovely out in the country, are often dull and wanting life in smoky London. Everybody who loves a telling blue Pansy for beds or borders should get Archie Grant.—D.

*

IBERIS CORIFOLIA.—Just let alone, with ample space in which to spread, what fine patches *Iberis corifolia* will make! I have a few plants which have grown to some 36 inches to 40 inches across, perfect masses of white flowers, and such neat little round trusses. What a capital plant for rockwork, especially where there are big bold patches to cover. There are kinds having larger trusses or heads of bloom, but none which bloom more freely or have such a neat dwarf close habit. It makes a fine companion plant to dark-bued *Aubrietias*.—A.

*

YELLOW AND WHITE BANKSIAN ROSES.—I send a small offering of May Roses. The little yellow Banksian Rose opened its first sweet cluster at the end of April, and is now a mass of bloom. The white Banksian was not quite so early, nor is it this year quite so floriferous as its sister, but its long garlands of blossoms are beyond reach and partly hidden by the foliage. For more than forty years, I am told, these lovely twins have flowered side by side, persistently contradicting the fallacy that yellow and white Banksian Roses never thrive as neighbours. They cover a large portion of the south front of the house, and have

to be severely thinned to keep them within bounds. This year the delicate and drooping wreaths of *Wistaria* blooms have got mixed with the tiny Roses, and the contrast of colour is lovely in the extreme. Climbing among the *Wistaria* is a Fortune's Yellow Rose full of buds, but as yet only two or three blossoms have fully opened. I enclose one, as also the constant pink China Rose, to complete my basket of May Roses.—SUFFOLKIAN.

*

AUSTRIAN COPPER BRIER.—The Briers, and this one especially, make up for their very short season of bloom by their charming qualities. This year the Austrian Copper Briers are more intense in colour than I have ever seen them; for two or three years past they have been so colourless, that I feared we had got a bad sort. The double Persian yellow (best of the doubles) is also finely in flower. They are beautiful together in a rather shallow bowl or deep dish.—J.

*

BEAUTIFUL SHRUBS FROM CORNWALL.—I am much interested in the articles which you have lately published on Sikkim *Rhododendrons*, and venture to send you a photograph of a plant of *Rhododendron Aucklandi*, which has this year produced upwards of 100 heads of flower. The flowers are now going off, but by post I send a small box containing a specimen also of *Edgeworthii* and *Gibsoni*, which have proved themselves equally hardy in the open air. *Embothrium coccineum* is also a very beautiful subject. It is a pity that it is not more cultivated. I also send a spray of the mauve variety of *Abutilon vitifolium*, as I observe that a correspondent has sent you the white form of this plant.—J. C. D.

*

A BEAUTIFUL RACE OF PANSIES.—I send for the "Editor's Table" a few Pansies of a rather novel strain. I hope they may reach you in good condition and please you. I am working them up to get size, but I find they do not cross at all well with the large fancy varieties.—A. RAWSON, *Widernere*.

*** These are a prettily margined strain and part of the series sold by the German Pansy grower at Lunenburg. They are so beautiful and distinct, that we hope Mr. Rawson will not succeed in intercrossing them with any coarser Pansy, such as the great overgrown French kinds.—ED.

*

THE CHINESE APPLE.—This is the most showy of all the *Pyruses*. We have at the present time plants 10 feet high, perfect pyramids of flower, and when they are seen with the sun shining upon them, they look lovely. *Pyrus floribunda* is a very showy variety, but it does best in a sheltered spot where the blossoms are protected from the cutting winds. *Pyrus coronaria* is also a very fine variety, coming into flower after the others are over and it is very sweet-scented.—T. B. F.

*** A beautiful wreath of the Chinese Apple (*Pyrus spectabilis*), which shows its usefulness in the shrubbery border at this season.—ED.

*

BRITISH ORCHIDS.—Mr. Webster says he has received *Orehis mascula*, very fine, from Ireland. I have never seen them finer than they have been this year in some of the Sussex woods and meadows. One spike which I particularly noticed had seventy-two flowers. Beautiful forms of various and distinct shades of colour with delicate and showy markings were in abundance, many of them good enough to merit a varietal distinction, but being only common British species they do not receive such attention from

the orchidist's hands. *Orchis purpurea* was very good in one spot, and embraced various shades of colour from a deep purple to a soft rose. Close by, *O. maculata* was profuse. The spikes were small and rather slender, with the flowers neatly disposed and of a whitish colour, the lip in many cases being very prettily marked. All of these kinds last well when cut. A selection of some of the best, arranged with the Grass among which they grew, is before me as I write, and though some people say they have an objectionable odour, it is not noticeable in the room.—A. H.

*

SCARLET MONKEY FLOWER.—What a brilliant flower this is, and how interesting to see how the rich colouring is produced, by a transparent glaze of red over a ground of strong yellow; if the flower's portrait were to be painted, the rich colour could only be got in the same way. The same contrivance gives the strong colouring of the Austrian Copper Brier. This little Monkey-flower likes to be cool and damp at the root, with sun and free air overhead.—G. J.

* * * This seems distinct from the Californian scarlet *Mimulus*, and is, we suppose, a dwarf and beautiful strain of *cupreus*.—Ed.

A WATER ROOF FOR PLANT HOUSES.

We saw lately in one of the Royal parks a novelty in the roofing of glass structures, which is more distinct and interesting than most things presented to us as patents and novelties. It is simply a flat, well-constructed roof, with an inch or two of water above it. It is capable of being tested easily in a variety of ways, and is, we think, worthy of trial. Cool houses, ferneries seem at first to be the most fitting structures for the system, but it may be useful in other ways. The following is a description of the invention by Mr. T. C. March, who has developed it:—

The essence of the invention is that all light and heat shall, before reaching plants, be made to pass through a shallow surface of water resting on glass. The interposition of even so slight a depth as 2 inches of water between the atmosphere and plants under glass controls temperature in a very remarkable manner, entirely protecting vegetable life from frost in winter and from excessive radiant heat in summer, results which are calculated to effect great saving in fuel and other cultural expenses. There is no mechanical difficulty in applying the water surface to the protection of plants. A shallow tray or cistern is made with a glass bottom, on which the water rests, and this transparent cistern, which may be called a water-light, fits closely over an under-frame containing the plants, moving backwards and forwards on a sill or rail in the manner of an ordinary garden light. The under-structure may be of wood like a garden frame, of brick like a pit, or of brick with glass sides like a greenhouse, but in either case the sides and ends must be of equal height, so as to give a flat roof and keep the water level. Glass and water are equally transparent, and by the above arrangement plants not only have the ordinary protection of glass, but the advantages due to the peculiar properties of water.

The immediate object I had in view in growing plants under cover of water was to obviate the necessity of artificial heat in the treatment of half-hardy plants. Water underlying ice in shallow vessels is always at 32° Fahr., or just above freezing point, and it appeared reasonable to conclude that a frame or house covered by water would not be colder than the water itself. Numerous experiments carried out at Kew Gardens and other representative establishments

through the whole of the late severe winter have proved this supposition to be correct. The result has, in fact, been more favourable than was anticipated, for the reason that the glass surface which holds the water adds to the protection by preventing the escape of heat, and it may be taken as proved that in all structures covered by water and otherwise properly protected, 35° Fahr. is the extreme amount of cold to which the plants will be exposed. This limit may possibly be further reduced, but, taking it at 35°, it is clear that many plants, such as Azaleas, Camellias, Cinerarias, Tea Roses, Cyclamens, Pelargoniums, and other bedding plants, may be grown on this system all the winter without artificial heat, thus avoiding the expense of heating apparatus and fuel, a result of some general importance, but more especially a gain to the numerous small cultivators near great towns who delight in keeping a few plants from year to year, but cannot afford either gardener or heated greenhouse.

In addition to the treatment of half-hardy plants in cold houses or frames as above described, the system of water-protection may be extended to heated houses with the object of saving and regulating the supply of fuel. In structures limited to 35° little heat is needed, and the amount can be given with certainty, which is of consequence on cold winter nights. The conditions provided by water-cover all tend to economy in fuel, for not only does the water limit the cold of the external air, but it allows great reduction to be made in the area to be warmed, and also prevents escape of heat by radiation from within.

The winter management of plants under water cover demands certain precautions. Pits, frames, or other houses, unless made in double brick, must be guarded at the sides, &c., from frost, and a damp-proof flooring should be provided for plants in pots to prevent the rising of earth damp. Ample means of ventilation must also be found for the reason that plants are at times somewhat closely confined, and therefore need air on all favourable occasions. A straw hurdle or other stiff covering should be placed on winter nights over the water-lights to limit the formation of ice and to prevent breakage of glass from overweight of snow. It may be taken as the result of numerous trials that about half an inch of ice will be formed in the cisterns on cold winter nights if entirely exposed to the weather, but only one-eighth of an inch if covered up. The covering therefore saves all trouble of removing ice and replacing it by water. It is, of course, only put on at night, advantage being taken of the transparency of ice and water to give light during the day.

To those who care to go beyond mere practical results, it may be interesting to know that the protection of plants from frost is chiefly due to the liberation in the act of freezing of the large amount of latent heat existent in water. This heat so retards the formation of ice that 2 inches of water suffice for all protecting purposes. Were it not for this latent heat all the water in the cistern would be quickly turned to solid ice, and the protection of the warmer liquid being withdrawn the plants would be destroyed by cold. A formula has been given to me on high scientific authority defining the amount of heat developed by freezing water as compared with the burning of fuel in a stove. I should be happy to supply it to any who may take interest in such scientific matters.

Carrying the experiments beyond the winter season, another important property of water, that of absorbing the heat rays of the sun, begins

to influence the conditions of growth. During spring the water surface not only repels the night frosts, but protects the plants from hot sunshine during the day, being thus doubly useful at a very trying season. As summer advances this absorption of radiant heat comes further into play. Plants protected by water can be placed in full sunshine without any shading, thus obtaining the strongest light without injury from heat. In this respect water differs widely from glass, which admits the passage of radiant heat freely through its substance, as anyone may tell on the sunny side of a closed railway carriage. This heat pouring through a glass garden light concentrates within the frame, and quickly destroys plant life, unless air be given and shading interposed. Water, on the contrary, so retains the heat that the plants are never scorched, and although the water surface by long exposure to the sun becomes warm and gradually communicates heat to the interior of the frame, the process is slow and the burning effect of radiation entirely neutralised. This control of radiant heat is remarked by those who have conducted the experiments to have very important consequences in the cultivation of plants, for not only is shading rendered unnecessary, but ventilation, and consequently watering, become less urgent, and labour is proportionately saved. It also enables us to reduce the height of garden structures, inasmuch as it is unnecessary to give that lofty head room to plants which must be provided in glass houses to dilute the hot air which penetrates the structure.

As regards the general health of plants under water cover, apart from the protection which they obtain from frost and direct heat, the conditions are so far favourable that they have good light at all seasons and are placed close to it. Without the stimulus of heat plants grow less rapidly, but the habit of growth is good, and Pelargoniums, which have been kept in a cold water-frame since last December, are now comparing favourably with greenhouse plants of the same description. Experienced gardeners who have given a good trial to the water system have come to the conclusion that the moist, even temperature obtained is most conducive to the germination of seeds and striking of cuttings, difficult kinds of which have been successfully treated in this manner.

No doubt water protection will suit some plants better than others. Cinerarias, for instance, are reported to do better under water than in heated pits or greenhouses. Others may do less well. The conditions being quite new, it can only be ascertained by experiment how far they favour the growth of particular plants, and it has yet to be seen whether strong light without corresponding heat will influence the colour of leaf or flower. To conclude, I can only hope that the facts above recorded and the inferences drawn may be strengthened by experience, and that the invention may prove to be of some use in the cultivation of plants under glass.

Notes from Suffolk.—Now blooming profusely is the lovely pink *Magnolia* (*Magnolia purpurea*); the *Magnolia Halliana stellata* is perfect in form and delicious in perfume. Is it really quite hardy? The blossoms look as delicate as those of the *Gardenia*. Hereabout the cold spring seems to have been less injurious than was anticipated. Lilacs, Laburnums, Ceanothus, and flowering shrubs in general are a mass of bloom, or promise of bloom. The *Rhododendrons* are coming out well, and the sweet, though little esteemed, *Barberries* are displaying their myriads of scented golden bells. In the fruit gardens and orchards the Apple trees are laden with bloom, and the Pears, Cherries, and Plums have been lovely in their snowy beauty; moreover, the fruit seems well set.—SUFFOLKIAN.

STOVE AND GREENHOUSE.

T. BAINES.

TERMINALIA ELEGANS.

MANY of the most beautiful plants that have been introduced are now so much neglected, that it is more than likely they will ere long be lost to cultivation. Amongst these is *Terminalia elegans*, which in small-growing, fine-leaved plants stands out conspicuously for its elegant habit of growth and the exquisite markings of its leaves. Speaking from memory, I should say it has been in the country about twenty years. When it first became known it was often met with in collections of warm stove plants. For, being a native of Madagascar, it requires warm treatment. It is an evergreen plant very like some of the *Aralias* in appearance; the leaves are deep green, the mid-rib bright red, with a network of the same colour running through the whole. Like many of the *Aralias*, it retains its foliage for a considerable time, and is altogether one of the most beautiful small-growing variegated subjects in existence.

It is easily grown, provided it gets sufficient heat and the leaves are kept free from insects, but if these are allowed to remain on the plant, they quickly destroy the colour and appearance of the leaves, causing the older ones to fall off and leave the base of the plant bare much sooner than would naturally be the case.

The ordinary method of propagation is by grafting; it will succeed on any of the small-growing *Aralias*, such as *A. Veitchi* and others of a like character. The grafts should consist of pieces of the stem—single eyes with enough wood below so as to admit of their being inserted in the stock wedge fashion. The grafting may be carried out at any time when there is warmth enough available to effect a union and excite the buds into growth. During this time it is necessary to have the newly-grafted plants in a confined atmosphere, such as a propagating frame kept moderately close. When the union is complete and top-growth has begun, the plants must be gradually inured to the full air of the house, after which they should be stood close to the glass where they will get plenty of light, for with this plant, as with all others that lose their appearance when the bottom leaves fall, it is requisite that the growth from the first should be made under conditions favourable to the foliage being hard and firm.

Propagation by grafting with this and other things of a similar description is not always convenient in private gardens, as the requisite stocks are frequently absent, in which case the plant in question can be increased by root-cuttings. These should consist of bits of moderately strong roots cut into pieces about an inch or so long, and inserted in pots filled with sand. The upper ends of the cuttings ought to be slightly above the surface of the sand. They should have a temperature of 75° or over, keeping them moderately close. So managed they will soon begin to grow and push shoots, when more air should be given. When a few leaves are formed, move them singly into small pots, drained and filled with fibrous peat and some sand. As already stated, the plant enjoys plenty of heat. Like most ornamental-leaved subjects, this *Terminalia* requires to be kept shaded in bright weather during the growing season, otherwise the foliage is liable to be injured.

Early in spring is the best time to propagate by root-cuttings, as then the young plants have the growing season before them in which to acquire strength; but the middle of summer is not too late to carry out the work, there being

still time enough to get the little plants sufficiently established to enable them to live through the winter, during which season the night temperature should not be lower than 60°. Early in spring move into larger pots, regulating the size according to that which the plants have attained. In the second summer they will grow fast, so that by autumn they will be very effective when placed on the side stages of the stove. Pots a size or two larger will be required when the spring again comes round, and it is during the ensuing summer that the plants will be at their best, as if all has gone well they will have attained a height of from 18 inches to 24 inches, and be fully clothed with leaves in perfect condition. After this the lower ones may be expected to gradually lose their colour and fall off, but in their later stages the markings usually come out more vividly than when the leaves are in full vigour. When the plants get bare at the bottom, it is best to head them down to within a few inches of the base, and when they have broken, the shoots may at once be

all the better if rested a little during the winter by keeping them slightly dryer at the roots. This drying practice, however, must not be overdone, otherwise it will do far more harm than good. Cuttings of these shrubs, taken when the plant is in a growing condition, strike root without difficulty, and I have also ripened seed and raised plants therefrom, but the progeny differed little, if any, from the parents.—H. P.

FREESIA REFRACTA ALBA.

THE bulbs from which the accompanying woodcut is engraved were grown in a pan. The pan contained 15 bulbs, which bore 318 blooms. I have also flowered this year seven pots, each 5½ inches in diameter, with five bulbs in each, averaging 112 blooms per pot, the best specimen carrying 128. The greatest number of blooms produced by one bulb was 35, and the greatest number on one scape 8; I have, however, one scape in the open ground that is carrying 10 buds. With me they do exceedingly well planted out under a south wall, and flower without the

Freesia refracta alba. Engraved for THE GARDEN from a photograph sent by Mr. W. Fitzherbert.

reduced to one, retaining the best, or, if stock is required, the whole may be allowed to grow until large enough to make cuttings. Those to spare should be taken off with a heel, and if treated like the cuttings of other plants that require a brisk heat, they will root and soon grow to an effective size. During the growing season the plants should be syringed freely once a day, which will have the double effect of keeping the leaves bright and clean and also of keeping them free from insects.

Franciscea confertiflora.—The *Francisceas* are now but little grown as stove flowering plants, yet they are highly ornamental, very distinct, and continuous blooming, as if in good health they will flower for some months. *F. confertiflora* is one of the best, the colour of its flowers being a sort of violet-purple, becoming paler with age. We have some little bushes of this which have been in flower for the last month, and with a little attention in the shape of stimulants, they will continue to bloom during the summer. These *Francisceas* will do well under conditions favourable to the general run of stove shrubs, and will flower

slightest protection, as do *Sparaxis*, *Ixias*, &c. I have now grown *Freesias* for five years and with unvarying success; in fact, I am more certain of a good result with them than with *Hyacinths*, *Tulips*, or any other bulbs. They have absolutely cold treatment from beginning to end, and are potted as early as the bulbs can be procured. Their delicious fragrance, graceful habit, and simplicity of culture should bring them into more general favour than they seem to enjoy at the present, judging from the infrequency of their appearance at shows or in private collections. *F. Leichtlini* is another variety that I have grown, but *F. refracta alba* is, to my thinking, preferable in all respects.

W. FITZHERBERT.

A beautiful stove climber is *Hexacentris mysorensis*, which for the past few weeks has made the roof of the great Palm house at Kew gay with its drooping clusters of curiously shaped open-mouthed flowers. The colour is a clear yellow, deepening to orange, and these tints blend with the rich venetian red tints of the corolla lobes. It is a plant of exceptional merit—one that has few equals

as a stove climber for early summer flowering. I once saw a roof of a small stove entirely festooned with it, and was a brilliant and most uncommon sight. It is a stock plant at all the big nurseries, and is easily grown. —W. G.

MAGNOLIA CAMPBELLI AND M. FUSCATA.

UNTIL seeing Mr. Burrell's communication (p. 442) respecting *M. fuscata*, I was not aware of Mr. Gumbleton's remarks (p. 304) on what I wrote respecting this species and *M. Campbelli*. Mr. Gumbleton says that I am not acquainted with these Magnolias. May I inform him that what I had to say about the plants in question, like any others that I happen to treat of, is invariably founded on what I have experienced in their cultivation. If I have anything to say about a plant that I only know through seeing it in the hands of others, I say so. Some years back a plant of *M. Campbelli* came into my hands, and was turned out in the border of a cool house and trained against the wall in the way I advised in my notice of this and *M. fuscata*, which species already occupied a place on the same wall. *M. Campbelli* grew well, but not too vigorously; in fact, knowing the character of the plant, I was careful, in preparing the material for it to grow in, not to give anything that would favour luxuriance. It flowered the third season after planting out and the two following years, when it came to an untimely end through a break-down in the heating apparatus.

The flowers were very large—from 9 inches to 10 inches in diameter. White was the prevailing colour; they were whiter than those of the common variety, *M. Soulangeana*; hence my describing them as white. If required to be quite accurate, I should say they were white, slightly shaded with pink. I named China as its native country for the reason that I have always understood that the first introduced plants came from there. How far this is correct I know not. Messrs. Backhouse, of York, have *M. Campbelli* trained on a wall in a rather low house, where it grows well, but, I believe, does not flower, which latter circumstance is attributed to the influence of a warm chimney that is in or against the wall immediately behind where the plant stands. Some years since Messrs. Backhouse had it in a cold pit, where it flowered. In this case the colour of the flowers, I understand, was like that of the old blush China Rose, much darker than they were with me. This difference accords with Dr. Hooker's description of the plant in Sikkim, where the colour is said to "vary from white to deep rose or almost crimson," which upsets Mr. Gumbleton's assertion when he confines them to deep rose.

I am generally careful not to give loose descriptions of any plant I write about, but in the hurry one sometimes may make a slip. In speaking conjointly of the merits of the two Magnolias in question, in place of saying they bear fine flowers, I intended to say that *M. Campbelli* had fine flowers, and that the flowers of *M. fuscata* were finely scented.

Mr. Gumbleton tells us that *M. Campbelli* is unfit for growing on a wall in a plant house, giving as his reason for coming to this conclusion that it grows naturally too large to admit of its being confined within a house. What of the scores of species of plants that are grown successfully and for an indefinite time in stoves and greenhouses of ordinary dimensions, and which in their native habitats reach two or three times the size that the houses they are located in would admit of their attaining? For the opposite reason of its being too small a grower, Mr. Gumbleton says that *M. fuscata* is unfit for growing against a wall. Such reasoning as this is a fair example of the mistakes those fall into who do not hesitate to speak with confidence respecting the cultivation of plants that, by their own showing, they know little about. In THE GARDEN (p. 463) Mr. Gumbleton now admits that his opinion about this plant rests on nothing more than what he has seen of it growing bush-fashion at Kew and what he has done with it in pots, the result of which seems to have been that it grew very little and very slowly with him.

With me it made shoots annually from 10 inches to 15 inches long, covering a space 10 feet wide by 14 feet high, and would have done more than this if required.

Plant growers who know how to manage the things they take in hand vary their treatment in accordance with the strong or the weak-growing nature of the plants they have to deal with. Mr. Burrell gives some advice as to how *M. fuscata* requires to be managed, as shown by the free growth that follows his heavy dressing with cow manure. I gave the plant soil as rich as I thought the roots would bear, and in addition the surface had 2 inches of rotten hot-bed manure put on every year, besides which it had manure water once a fortnight through the growing season. As a matter of course, with *M. Campbelli* the opposite course was taken, nothing in the way of stimulants being given. Had it been treated like *M. fuscata*, its branches would no doubt have been struggling to get through the roof in very little time. T. B.

DOUBLE PRIMULA SINENSIS.

THE fine double forms of the Chinese Primrose, introduced by Mr. R. Gilbert, are so valuable for warm greenhouse decoration when in bloom, that they will continue to be grown, and will, I think, hold their own against the new semi-double forms that can be raised from seed. One or two others have been added to the group, and the following are varieties that are procurable: *Rubra grandiflora*, pale rosy purple; *Miss Eva Fish*, pinkish lilac, deepening to rose; *Earl of Beaconsfield*, rosy salmon, deepening to carmine, fine, and distinct; *Balfour*, deep salmon-carmine; *Annie Hillier*, delicate pink; *Princess*, white, spotted and flaked with crimson; and *Marchioness of Exeter*, double white, tinted with blush. As Mr. Geo. Stevens succeeds so well in growing the old double white Primula in the soil in which his specimen Chrysanthemums were grown during the previous summer, I think it probable the varieties named above would do in such a compost. It is made up of good loam, some decomposed manure, rough sand, and pulverised bones, and when the Chrysanthemums are turned out of their pots the roots and soil are thrown together in a heap in the open air, and then in April and May following it is used for potting up the double Primroses, and it appears to suit them admirably. That they can be grown into plants of large size has been shown by Mr. W. Elphinstone, of Shipley Hall Gardens, Derby, who from spring-struck cuttings makes plants of large size and finely grown and flowered.

The difficulty of propagating these double Chinese Primroses is urged as an objection against growing them. Mr. Stevens freely propagates the double white variety by heaping up Cocoa fibre about the stems of the shoots, and they root into it, and then they are cut off and potted, and that too without giving them any severe check. Mr. W. Elphinstone cuts half way through the stem, then powders the cut with fine charcoal, and by pegging down upon the soil without, however, severing from the parent plants, roots are put forth, and so plants are formed. Then there is the practice of taking off cuttings and striking them in a gentle bottom-heat, which is also found to answer. It is sometimes said that the gardener of to-day fights shy of growing plants that are difficult to manage. Some, however, take in hand plants of this character and succeed with them, and it is they who merit our thanks if they do not attain to some higher award. R. D.

Leschenaultia biloba major.—At the last Regent's Park exhibition a number of plants of this *Leschenaultia* were shown, and the intense colouring of their beautiful blue flowers made one long for a return to popular favour of this and many other of the New Holland plants. For some years this beautiful plant has been well grown by Mr. Balchin, of Hassocks, near Brighton, the clear atmosphere of the South Downs just suiting it. A coloured plate of this was given in THE GARDEN two or three years since, at which time it certainly came as a great surprise to many that this plant was still grown

successfully in England. The *Leschenaultia* will succeed under much the same conditions as most of the greenhouse Heaths, its greatest enemy being mildew during the winter, to prevent which plenty of fresh air is necessary. This *Leschenaultia* is propagated by cuttings of the young shoots put in during April and May. They must be covered with a bell glass and in a gentle heat will soon strike root. —H. P.

Hydrangea stellata flore-pleno.—This is a very pretty and distinct variety of *Hydrangea*, but though known for many years it is but little cultivated, no doubt owing to the fact that it is much less vigorous in constitution than the commoner kinds, and when subjected to the same treatment it rarely does well. Bearing this in mind, it is easy to obtain thriving specimens, either in the shape of small plants with a single head of bloom, or as bushes with each shoot terminated by a flower cluster. In this variety the sterile flowers are double, and of a pleasing shade of pink. Like all the rest of the section, they last a long time in beauty if favourably situated. —H. P.

Acrophyllum.—A single plant comprises this genus, although it is nearly allied to *Weinmannia*, from which it may be distinguished by wanting the disc to the flowers. Individually the flowers possess little beauty, being small and white, but in the aggregate they are exquisite. For soil, use good fibrous sandy peat, broken up roughly; drain amply and water freely during the growing season. The shoots should be cut down below the flowers each season. *A. venosum*, sometimes to be found in collections under the name of *A. verticillatum*, is an erect, free-growing plant. Stem and branches terete; leaves in whorls of threes; these are sessile, coarsely toothed, smooth, coriaceous in texture; upper side coppery green, glaucous beneath. Flowers white, suffused with pink, produced in dense whorls round the upper part of the branches for about 6 inches, which is destitute of leaves, resembling somewhat the inflorescence of a *Spiraea*; whilst the apex is crowned with a whorl of leaves. It is a very ornamental plant, useful alike for exhibition purposes or home-decoration. It blooms during May and June. Native of Tasmania.—G.

Fragrant Chrysanthemums. If these flowers possessed a fragrance they would be much more highly prized. The varieties, all of which smell like Violets, are of a limited number. The scent of some varieties, more especially that named Mrs. Langtry, is sufficiently strong when several plants are growing together and flowering freely to pervade the whole house. When the sorts which I shall name are cultivated for their fragrance alone, they should be managed so that they flower freely, and in the case of Dr. Sharpe and Frogne, two reflexed kinds, the buds of these should not be selected too early, or the flowers will be much paler in colour and of irregular shape, particularly the former. It is wise to allow this variety (Dr. Sharpe) to perfect a number of blossoms, which it will do if the shoots are pinched when the plant is 4 inches high, and again when the subsequent branches are 5 inches long. After this one more stopping will suffice, allowing the shoots to grow away at will, thinning out the branches and flower buds according to requirements. Mrs. Langtry is a variety of a pink shade of colour, flowering as a bush plant profusely all the way up each stem, and should be allowed to perfect all its blossoms. Patience, another single-flowered variety with fringed flowers, is scented, but in a less degree. Dick Turpin, an Anemone-Pompon variety, bright magenta, with a yellow eye, of dwarf habit, flowers freely and possesses a powerful Violet fragrance. To have bushy plants, the shoots should be pinched about three times in all, allowing all the flower buds to develop. —E. M.

SHORT NOTES.—STOVE AND GREENHOUSE.

Double glazing.—It is a benefit in a climate where 40° below zero is not uncommon. It adds to the temperature of a house from 10° to 12°. There is trouble in permanent double glazing from dust getting between the glass. We have overcome that defect by the use of neat light sashes that are glazed without putty, and fitted in the inside. They can easily be taken off and cleaned, say about once in two years. Double glazing in a measure prevents drip. We grow here Orchids, Roses, Camellias, &c., in the different houses, all

more or less double glazed. I should say double glazing was entirely unnecessary where the temperature did not fall lower than 15° to 20° below zero.—AMERICAN FLOREST.

Diseased Crotons.—I send you a few Croton leaves which are affected with some disease. The plants have been in the same house for nearly nine years, and the disease first made its appearance about twelve months ago. They have had the same treatment during the whole time I have had charge of them. The small plants, as well as the specimens, are affected.—W. R.

Impossible to say what the disease can be unless we know the treatment. Have they been syringed lately with any insecticide containing paraffin?—Ed.

THE AMARYLLIS.

The remarks in THE GARDEN by "T. B." (p. 164) on seedling raising are very interesting, but the most vigorous species and varieties are not recommended, nor are the hybrids from Ackermann and Leopoldi likely to give the best results. In fact, I cannot get seeds from hybrids of either of those, and have tried year after year to obtain them. The best Ackermann cross known to me is a variety named Cheloni. I bought a bulb of it for two guineas some eight years ago, and have tried to get seeds from it ever since, but have failed. Again, the best Leopoldi cross is a variety named John Neal, and it is a fairly good grower, while Cheloni is not; but I cannot get a seed-pod to form on the former, nor have they been able to get it to seed in Messrs. Veitch's nursery. By using the pollen of John Neal on other varieties several years in succession I have obtained one single seed and raised a plant from it, but this was not obtained until many crosses were made and failed. Another serious fault with Leopoldi and Ackermann is that they produce but two flowers on a scape; whereas, the best varieties will produce six, and as many as three scapes from one bulb. Those who are desirous of raising seedlings ought to obtain the best varieties at present in cultivation, and, all points taken into account, there is none to equal the Empress of India type. This handsome variety was introduced by Messrs. Veitch, of Chelsea, and has been the parent of many of the best varieties, which in their turn produced seeds freely. Dr. Masters is an excellent variety either to use as a seed or pollen-bearer. I have successfully crossed this with Empress of India. There are seedlings from these two—improvements on both, but they are yet expensive. When Messrs. Veitch introduced that remarkable variety named The Giant, and exhibited it with sixteen immense flowers from one bulb, I thought we had found the progenitor of some remarkable varieties, but it seems to be very difficult to get it to produce seeds at all. The best light coloured variety for the production of seeds known to me is Enchantress; it produces four and five-flowered scapes, three from a bulb. I do not say that it produces such handsome flowers as the novelties of this and last year, but it is not expensive, and none excel it in vigour. Lady of the Lake, Her Majesty, Flowerdale, Hon. and Rev. J. F. Boscawen, and The Giantess are the best of the new light-coloured varieties; they are all superior to the older varieties, but one cannot tell until a trial has been made how they will come out as seed or pollen-bearers.

"T. B." also states that the plants should have plenty of light. Many growers might think from this remark that shading is unnecessary, or probably injurious. I may say that we shade from the sun all through the summer months. Even such a vigorous variety as Empress of India will not stand the direct rays of the sun; the leaves become rusty and die off prematurely. Probably it is the exposure to too much sunshine that causes red spider alluded to by "T. B." We are seldom troubled with this pest, nor do we syringe the plants daily. The vigorous kinds might not be injured by it, as they produce roots freely, but the weakly growing kinds that produce few roots would certainly suffer; the water runs down the leaves and is conducted to the bulbs, which become too wet; the roots are killed, and the bulbs decay. Thrips are more troublesome, and it takes a great deal of fumigating with tobacco smoke to kill them.

I may add that I recently gathered the first ripe pod of seeds; all of them will be gathered by the middle of June. They ought to be sown at once,

and if carefully treated will produce good plants by the end of the season. Both seedlings and old-established plants require a bothouse temperature all through the summer months. J. DOUGLAS.

SEASONABLE WORK IN PLANT HOUSES.

GREENHOUSE.—HEATHS.—Those who propagate and grow their own stock of winter-blooming Heaths experience little difficulty in getting the plants to move freely after they have bloomed, as compared with those who usually purchase what they require when in flower, or about to flower. The reason for this is that home-grown plants are not likely to have their future well-being endangered by being over fed; whereas it often happens that the plants which come from the hands of the great growers are so overdone with artificial manure, given during the season that immediately precedes their blooming, that many never recover, even when carefully treated after they have flowered. There is little difficulty attending the propagation of the autumn and winter-flowering section of Heaths, as most of them are soft-wooded and quick growers. Cuttings put in towards the end of summer, if fairly attended to, will be well rooted by spring, early in which they should be potted off. Young plants that have been raised in this way and are now in small pots should be kept in a cold pit or frame, with the pots stood well up to the glass on some moisture-holding material, for if they do not get plenty of light it is useless to expect them to do well. Give a little shade in bright weather; they must be well attended to with water. Stop the shoots so as to lay the foundation for well-furnished specimens. Plants that are a year older and now in larger pots require to be similarly treated, except that less shade will be needed, and they may have more air; plants of this size should also have their shoots pinched back moderately. Larger plants that are in the pots in which they are to flower may now be stood out of doors on a bed of fine ashes, or, still better, in a shallow pit, where the lights can be drawn off them and replaced if heavy rains occur. Give the requisite attention to assist the growth, so that the plants may gain sufficient size early in the season to admit of their being in a condition to bloom well. Manure water may be given once a fortnight or so, being careful not to apply it too strong. Plants that have flowered and been repotted after being cut in should be kept under glass until the roots have got some hold of the new soil, after which, the sooner they are put out-doors the better, treating them as recommended for the younger stock.

ERICA DEPRESSA.—This old species is a slow grower taking many years to attain full specimen size; but, as against this, it is much less liable to get out of order than any other Heath I have ever grown. In proof of this, when Heaths were more grown than at present, it was no uncommon thing to meet with specimens that were twenty or thirty years old. Its flowers are also very enduring, lasting two months in good condition. But to succeed with this kind it must be exceptionally treated by exposure to the open air; it cannot be depended on to flower unless the plants are turned out where they will be under the full influence of the sun early in June, allowing them to remain so long in autumn as there is no danger from frost.

ROCHEA PALCATA.—Young plants that have been grown on from cuttings and are expected to flower during the ensuing autumn should be kept where they will get all the light possible with full exposure to the sun. Fleshy-leaved succulents of this character do not require any shading, however bright the weather may be. The plant does not need much root-room; for such as consist of a single growth 5-inch pots will be large enough. Examples that bloomed last year, and were shortened back when done flowering, should now be furnished with three or four growths. These may not attain enough strength to bloom the coming autumn, but if not already potted they should be at once moved into pots about two sizes larger. When it has reached this size this Rochea is seen to advantage; its dense, brilliant-coloured heads of bloom, when several together, are very effective.

STOVE.—GARDENIAS.—When Gardenias are well managed they keep on producing successional flowers, more or less, as long as the plants make free growth. With plenty of heat in a good light house they soon attain a large size, but unless they have a proportionate amount of root-room, the growth comes thin and weak and the flowers small; this they will do if under-potted, even when manure water is given them. Therefore, unless there is room to accommodate large specimens, it is better to either discard such as are getting bigger than desirable, or shorten their branches well in, and after the plants have broken into growth turn them out of the pots and shake away a considerable portion of the old soil, putting them in others a size or two larger. So treated, there is yet time before the end of summer for them to make strong growth that will bloom. Young stock struck from cuttings early in spring should be pushed on so as to get all the strength possible into them before the end of the season, for though the naturally free disposition of the kinds usually cultivated is such that they will flower in a small state, yet the quantity and size of the flowers are fairly proportionate to the strength the plants have attained. Gardenias are free rooters, and as soon as the pots which the little plants are now in get full of roots they should be moved to others two or three sizes larger. Brisk heat, with plenty of light, a moderate amount of atmospheric moisture, no stint of water to the roots, and freedom from insects are necessary to grow Gardenias well. The small *G. citriodora* requires proportionately less pot room, but the more size the plants attain the greater quantity of flowers they may be expected to bear; consequently when the soil gets well filled with roots larger pots should be given. This species does not need much interference with its branches, little or no cutting in will be wanted, except removing the points from any shoots that take an undue lead of the others.

NEPENTHES.—At one time these singular and interesting plants were rarely met with in private gardens; here and there a plant of the old *N. distillatoria* or *N. phyllanphora* might be seen, but for many years after the large, beautifully-spotted kinds, such as *N. Rafflesiana*, were well known, few people undertook their cultivation, and of those who made the attempt, still fewer succeeded in doing much more than keep them alive. To meet with a plant well furnished with large-sized pitchers was rare. Now they are much more grown, and deservedly so, for it would be difficult to name any plant that attracts more attention than a well-managed example. Nepenthes are by no means difficult to manage, provided their requirements are understood and attended to. It is sometimes supposed that to grow them well they require a house to themselves, but this is quite unnecessary. The best examples I have ever seen were grown in a house along with a mixed collection of stove plants, consisting of kinds that require or would bear a high temperature. Plenty of heat all the year round is the first essential to success with Nepenthes, plenty of moisture both in the atmosphere and to their roots, and plenty of light, with shade in bright weather, are all necessary to the production of large, well-developed pitchers. Where any of the above conditions are wanting, the plants may grow fairly and keep healthy, but only a few of the leaves, consisting of such as are produced during the height of summer, will form pitchers. Nepenthes make comparatively few roots, and these of the most fragile nature, far more so than any other plants with which I am acquainted; consequently, if in repotting there is any attempt to shake away any of the old soil, the roots often get so much broken that it is more than likely the plants will not get over it. Yet the old material must be got away, for however full of fibre and calculated to last it may be when the plants are put in it, the saturated condition the roots require its being kept in causes it to get so close and pasty, that they will not continue healthy in it. The best way to get the old soil away is to place the ball in a vessel filled with tepid water, and with the fingers to gently get the roots clear of it; there must be no attempt at disentangling them, or many will get destroyed. All that is

necessary further is to replace the plants in the same pots if large enough, or to give others a size or two larger; the compost should consist of the best Orchid peat full of vegetable matter, mixed with chopped Sphagnum, crocks and sand, soaking the material well as soon as the potting is completed. They require water every day during the growing season, and should have it two or three times a week in winter. In summer they ought to be syringed overhead freely every afternoon. When suspended with their heads well up to the roof—the best position to grow them in—a large volume of air should not be admitted near where they are hung, and a piece of thin canvas should be placed over the opening to break its force. If too much top air is given, it dries the atmosphere too much. The best time to repot is about March, but, where the season is allowed to advance further before much additional heat is used, the potting may be deferred until the present time.

SARRACENIAS.—These plants will now have matured their season's crop of leaves, but they must be plentifully and regularly supplied with water at the roots; once a day all through the summer is not too often. The nearer the glass the plants are stood, provided they do not absolutely touch it, the higher their colour will be. I do not approve of syringing the tall growing species overhead, as it tends to make their leaves weak. They are subject to the attacks of thrips, and the stock must be carefully looked over often to see that these pests do not gain a footing. If insects remain undisturbed for even a short time, the foliage will be disfigured. Fumigating with Tobacco or washing with clean water is the best means of destroying the insects. T. B.

TOP-DRESSING AND ITS EFFECTS.

Is the value of a suitable top-dressing for various subjects, both in pots and planted out, so fully realised as it deserves to be? I think not. We pot and repot, plant and replant very frequently, much oftener than there is any need for if only we adopted the more simple and economical method of renewing or re-invigorating from the surface. Every time we repot many kinds of plants there is a danger of injuring them in some way. A plant may not take readily to the fresh soil, and unless very carefully watered sourness results, the plant soon assumes a sickly hue, and its removal from the bad soil and introduction into a smaller quantity of more suitable compost is the only way to save its life. As a rule, however, plants thus badly injured very frequently never recover satisfactorily, and are only fit for the rubbish heap. I do not wish to say that top-dressing is at all times better than giving plants a shift into larger pots, but what I am anxious to prove is that it is often wiser to top-dress rather than repot. I do not think it will be disputed that there are more plants annually lost from being over-potted than from any other cause, and if it is good for trade it is not always good for either the owners or those responsible for the losses.

Hard-wooded plants, including Ericas, Epacrises, Hedaras, Azaleas, Pimeleas, and Phenocomas, in the hands of comparatively inexperienced growers very rarely recover from the liberal shift frequently given them. Repotting is necessary when either the soil about the roots is sour, or when the pots are crowded with roots. In the former case much of the soil should be carefully picked away from the roots and the plant repotted in a smaller pot, while the root-bound plant may well receive a shift into a fresh pot only just large enough for the compost to be properly packed round the balls. When potted in a dry state, or the old soil is subsequently allowed to become very dry, the chances are that the plant will die. If, instead of repotting a plant not really suffering from being root-bound, top-dressing was resorted to, there would be much less risk, and the fresh compost would sustain the activity of the plant for at least one season. All the plants named delight in a peaty compost, and ought to be top-dressed with nothing but good sandy fibrous peat. It is advisable to first water each plant if at all dry, and carefully remove any sour surface-soil to the extent of well barring

the roots. This admits of more space being given to the fresh, well-rammed soil, and this coming into immediate contact with the roots is soon taken possession of by them. The one great drawback to this top-dressing is the difficulty experienced in discovering when the plants require more water. The top-dressing may be quite wet, and yet the bulk of the soil underneath in want of water, and *vice versa*. It will be found the safest course to either test them by lifting or prodding through to the old soil with a pointed stake. Such firmly-potted, fibrous-rooted plants ought always to be watered before they are quite dry at the roots, or otherwise it is almost impossible to re-moisten the soil other than by dipping in water.

Orchids, again, are being constantly repotted, more often than not to their great injury. The majority of them do not require much compost, and some of the best plants in the country are very rarely disturbed beyond what is unavoidable during the process of removing old compost and renewing with fresh. By all means turn out sickly plants from their pots, pans, or baskets, clearing them from old compost, washing the roots, and returning to smaller receptacles; but do not be in too great a hurry in repotting well-established plants. Such rough treatment destroys nearly all the roots clinging to the sides and a severe check is given. Well-rooted plants of most species rarely fail to flower, especially if not stewed up in a steaming hot-house. If just before the roots are active much of the loose old crocks, charcoal, and fibrous peat is carefully picked away, and fresh materials substituted, finishing off with a surfacing of fresh Sphagnum, is all that is needed in very many cases. We have a quantity of *Cypripedium insigne* that have been in the same pots for several years, and all they get is an annual top-dressing of turfy peat, our loam not being sufficiently fibrous for the purpose. *Cœlogyne cristata* requires much the same treatment, and will do well with or without the surfacing of Sphagnum. Several *Vandas*, *Acrides*, *Cattleyas*, *Cymbidiums*, *Dendrobies*, and the good old *Zygopetalum Mackayi* which we grow are rarely disturbed, and they all flower very satisfactorily.

Even the strong-growing *Stephanotis floribunda* will do well for years in the same pot or border, provided always the plant receives an annual top-dressing consisting, say, of equal parts turfy loam and peat and a liberal addition of old cow manure and sand. Nor do *Allamandas* require so much root-room as some imagine, but they must have occasional supplies of good fresh compost. The pots or pits being well filled with active roots, these should be further encouraged by a top-dressing such as recommended for the *Stephanotis*, or, if need be, of all cow manure. Bone-meal may with advantage be added to the top-dressing compost, and I should prefer that to the cow manure; but no artificial manure should be added, this sometimes injuring the tender roots, and it is a safer plan to sprinkle small quantities on the surface occasionally. The same remarks as to top-dressing apply equally well to *Bougainvilleas*, *Thunbergias*, and various conservatory climbers. *Dipladenias*, when well rooted, should also be top-dressed, but not with a heavy or rich compost. An Orchid-like mixture suits them far better, or only lumps of fibrous peat should be used.

What looks worse than a number of over-potted *Crotons*, *Dracenas*, *Ixoras*, *Cyanophyllums*, *Pandanuses*, and various other heat-loving plants? All may be grown to a great size in comparatively small pots, and will prove more serviceable and stand more knocking about than the over-potted plants. The latter certainly require much less water, but even if the root-bound plants suffer from a want of it they can be more quickly restored to good health than others that are sickly, owing to receiving too much. In addition to requiring more water, root-bound plants also need frequent supplies of some kind of liquid manure. It is owing to the neglect in this respect that numerous plants present a starved appearance, for which the only remedy would appear to be repotting. *Anthuriums* and *Alocasias* delight in a rough peaty compost, with charcoal and crocks added, and if treated to annual

top-dressings of this, with a surfacing of Sphagnum, will do well in the same pots for years. The *Eucharis* roots freely near the surface, the fibres soon taking possession of a top-dressing such as advised for the *Stephanotis*. Instead, therefore, of frequently disturbing them at the roots, it is a wiser plan to keep them in good health with the assistance of surface-dressings and plenty of soot water.

As a rule, the Grape Vine, as well as various other fruit trees, thrives most satisfactorily when the roots have easy access to a supply of fresh compost, and at this time of the year it is best applied to the surface of the borders. According to my experience, quite a limited amount of fresh compost does more good than a quantity of liquid or solid manure applied to an exhausted or inert border. In the latter the roots can rarely be induced to form abundance of fresh fibre, and not much of the added manure is assimilated by the old and perhaps half-dead roots. It is too late to open a trench in the borders at a safe distance from the stems, re-filling with fresh soil, but the surface may yet be freshened up. After the old soil has been carefully forked away till the roots are met with in quantity and the border well watered if at all dry, give a top-dressing of 3 inches or 4 inches of fibrous loam, to which has been freely added lime rubbish, ashes from the heap of burnt garden refuse, half-inch or smaller bones, and a little partially decayed farm-yard manure. Into this the roots ought soon to find their way, and will do better service than the much larger "goose quills" that take possession of top-dressings of rich manure, and which seem to disappear with the manure. In some instances it may be necessary to further mulch the borders in order to prevent a too rapid loss of moisture by evaporation, but I much prefer a surfacing of rough strawy manure to that in a more rotten state. In this, as in the case of pot plants, the state of the top-dressing must not decide whether the border underneath requires water or not.

Cucumbers are very generally top-dressed, but the operation would be much more effective if only fibrous loam was used. Solid manure of any kind mixed with the loam may suit the plants for a time, but it soon clogs and excludes the air from the roots, besides encouraging the spread of those minute worms which often so badly injure the roots. Not only do we exclude manure from both the original heaps of soil, but none is added to the heaps subsequently. Turfy loam is the best form of top-dressing, this being given in small quantities and often. The roots rapidly take possession of this, and if well supplied with water and clear liquid manure, the plants will prove very prolific and continuous bearing. Any kind of liquid manure that will clog or gradually cake over the surface ought not to be used. Tomatoes require very similar treatment, no plant better repaying for frequent top-dressings and plenty of liquid manure. Melons are very rarely top-dressed, but if it is given them when the roots are most active, they spread freely into it, this materially assisting the plants to swell off a heavy crop. We top-dress with turfy loam of a clayey nature, to which a sprinkling of slaked lime has been added, and we have every reason to be satisfied with the results.

All kinds of hardy trees are benefited by good surface-dressings of loam and manure, and something of the kind is really necessary in the case of numerous choice trees planted in poor soil. In the course of levelling and forming pleasure grounds, it frequently happens the surface soil is muddled away, and as the subsoil is altogether unsuitable for most trees, small holes are dug and filled with good compost. This encourages the trees to grow strongly for a time, but unless they receive further assistance, either by having trenches cut round them and filled with good soil, or a quantity of the surface soil removed and replaced with the best compost procurable, they soon come to a decided standstill. It is unwise, though not altogether useless, to place a quantity of loose soil and manure on the surface, the best plan being to bare the surface roots, and on these place the compost. W. I.

Coloured drawings of Bromeliads.—We learn that the trustees of the Bentham Fund for Promoting Bota-

nical Science have purchased the coloured drawings of Bromeliads made by the late Professor Morren, of Liège, and that they will be deposited in the Kew herbarium. Several of the living plants were, we understand, also obtained for Kew.

FLOWER GARDEN.

NARCISSUS CALATHINUS VAR. REFLEXUS.

THE *N. calathinus* of Redouté differs from *N. triandrus* of Linnaeus only in the size of the corona. The latter is, however, a smaller plant altogether.

N. calathinus—the chalice-flowered Narcissus—is a much better name, as it describes the flower exactly, whereas the commoner name, *triandrus*, is a misnomer, having arisen through a misconception of Linnaeus, who overlooked the three stamens of the lower row. All this is clearly set forth by Mr. Burbidge in his "*Narcissus*," pp. 69–71.

I think there should be but one group, to include all these chalice-flowered varieties, and that *calathinus* should be the name for it.

In colour all these flowers are of a creamy white. The illustration is taken from a photograph, adjusted so as to give the exact size of the flowers.

The bulbs from which these flowers were grown were collected in the spring of last year in the north of Portugal. A friend of mine, Miss Stanley, had gone to reside there for the benefit of her health, and although no botanist, she very willingly complied with my request to search for Narcissi. I furnished her with sketches of every sort she was likely to find, and amongst others she was fortunate in collecting a large number of bulbs of the *triandrus* varieties, which were sent home by the next post.

On receiving these bulbs the flowers were too far gone for identification. The bulbs were planted in sand and allowed to ripen off. Under this treatment a large percentage survived, and bloomed freely in a cold greenhouse here.

Miss Stanley tells me that the children and country people in Portugal call this beautiful

good and rare in Dutch and Flemish varieties. Amongst the last a good number are new and not yet in commerce. There is also an unrivalled collection of Flemish breeders, violet and rose, in the most striking and brilliant colours, which deserves interest not only as breeders, but also as bedding Tulips. If they will break, there is every probability that they will give rise to a large number of first-rate varieties; but, still, they will be very valuable for bedding. The colours vary from pale porcelain to the darkest violet; from soft rose to the most brilliant red, and much more striking than *T. Gesneriana* and similar sorts. There are also light and dark brown shades, and a few which approach as near to black as this colour can be found in the vegetable kingdom.—X.

LILIES OF THE VALLEY.

WHATEVER is done in this country towards solving the problem, as to the possibility of growing Lily of the Valley crowns suitable for ordinary winter forcing equal to the sample obtained from Germany, merits generous consideration. There is reason to fear that growers for this purpose have to contend with much trade prejudice in favour of the Continental roots, but it can hardly be imagined that perseverance, combined with the production of a first-class home-grown sample offered at a moderate price, would not soon create a home trade. There seems to be no doubt but that what is done in Germany can be done here, and if it is possible to produce at home as good as can be obtained elsewhere, common sense seems to point towards its being done. Something towards a solution of this problem has been done at Twickenham, where Messrs. Hawkins and Bennett have for many years been developing a huge stock of their grand variety, the Victoria Lily, not in pots, but in large beds comparatively outdoors, for these beds are protected only during the spring, when some two or three are lightly forced, and the rest are protected by the aid of lights or thin canvas rolled down over the plants at night. The growers believe that the worst enemy to the successful cultivation of high-class Lilies of the Valley is found in spring frosts. Still, it is obvious that they regard this protection more needful as a shelter for the bloom than for the foliage, which seems hardy enough. But at Twickenham, owing to the exceedingly limited area of ground at disposal, the plants have to be literally crammed in thickly, and in a locality so near the Thames, moisture and fog might be expected to promote harm from frosts. Still, none is evident on the stock beds, which have no protection; hence, it seems evident that the shelter afforded is chiefly to assist the production of pure, unstained flowers. As evidence of the density of the growth in the more advanced beds, it is affirmed that these give in good crowns no less than 500 to 600 per square yard—a marvellous production, and it is hardly to be wondered at that the firm, finding themselves rather overdone with stock, are at length about to offer some to the trade. The present beds range from 7 feet in width to 150 feet long. Generally they have protection in the form of movable wooden sides and ends, but the ends have on the tops very stout pieces of quartering, through which pass long screws, to the heads of which are attached stout wires. These at intervals of 12 inches apart are strained tightly the whole length of the beds, some stout sticks being laid across as rests for the wires at intervals. On the wires light canvas is rolled down at night and back again in the morning, and as the blooming period approaches lights are laid on over the wires to give the flowers the desired finish. As a few of these beds have the advantage of a couple of hot-water pipes running through them, whilst others without heat are somewhat under the shade of trees, the blooming season is greatly prolonged, and the quantity of flowers obtained is so enormous as to seem, when mentioned, almost like exaggeration. A bed lasts for about six years if heated, and eight years if left unheated. The whole of the roots are then lifted out and sorted. In the meantime the soil is partly excavated and renewed, the bottom is trenched, and

Narcissus calathinus var. *reflexus*. Engraved for THE GARDEN from a photograph sent by Mr. W. Brockbank.

The two varieties merge into each other by such slight gradations, that if you have a large number of blooms before you it is almost impossible to say where *triandrus* ends, and where *calathinus* begins, or to differentiate the one from the other.

In the cases represented by our illustration the corona is so large, that it becomes quite evident that the flowers belong to *N. calathinus*. This will be seen at once on comparing them with Redouté's illustration, which is reproduced in a woodcut by Burbidge at p. 34 of his work.

The bell-shaped flower in our plate is, I believe, a new form of *calathinus*, requiring a new name. It differs from every illustration I have been able to find of *N. calathinus* in its corona, which is here campanulate in form, and of much greater size than is found in this class. The corona is of exquisite shape, the curves being beautifully delicate, and the trumpet mouth instead of being plain is well expanded and deeply crenated. There are other examples of *N. calathinus* having this campanulate form in my collection, and I think a class *Campanulæ flora* will have to be instituted to embrace them.

campanulate variety the Ave Maria. It was found in an Oak wood near the sea coast.

Since the above note was written Mr. Baker has identified this variety as the *N. reflexus* of Brotero. WM. BROCKBANK.

Brockhurst, Didsbury.

Tulips at Haarlem.—The Tulip beds in the nursery of E. H. Krelage and Son, Haarlem, at the Kleinen Houtweg, are now in full bloom. There are four beds of Tulips under two spacious tents, which cover an area of more than 7000 square feet. Two beds, each containing 700 bulbs, are planted with the greatest possible variety of Dutch sorts in violet, rose, and bizarres. There are two other beds under a smaller tent containing each 870 different sorts of byblomems and roses, all Flemish varieties of the most brilliant colours, and equalling those which in olden times were the models of the best Dutch painters. This Tulip show, which is now again opened for the third time, is later than usual this season, and will last till the middle of June, if the weather is favourable. It is the most splendid show of Tulips ever held in Holland, and probably has never been equalled. Besides these the collection of late Tulips of every description planted in the nursery is very large, and contains everything

ample manure added, as also is fresh soil, and the bed is replanted. Skilled labour seems needful for such work, as there is much patience and care needed in placing the crowns in the beds in lines and with perfect evenness. The first year, because the crowns are still plump, very good flowers are produced; the second year, because the roots are mostly engaged in establishing themselves, the flower production is less, but the third year finds strong crowns producing robust foliage and fine flowers. The process is simple enough, and with so many beds it is needful to renovate some every autumn, for November seems to be about the best season for performing this useful work. Annually, after the beds are established, a top-dressing of short manure is given to the beds. It serves the useful purpose of protecting the crowns from frost and fertilising the soil. Clay's fertiliser, applied in the spring, is also found a valuable stimulant, promoting glossiness in the leafage and finely developed spikes of bloom. The Victoria variety is one of the finest grown, and a glance over the Twickenham beds, luxuriant in foliage and crowded with bloom, shows that it has no tendency to blindness. What is so well done by Messrs. Hawkins and Bennett in their restricted area and in soil of only moderate quality, may also be done very largely in specially favoured localities which have natural deep soil, where the area is extensive and fruit trees give some useful shelter from spring frosts. A. D.

Cistuses.—There can be no doubt that the past winter has played sad havoc amongst these plants, either owing to the cold, the damp, or the heavy falls of snow. To the two latter most, if not all, the damage I think may be traced, for, however cold it may be, if dry and the air clear, they may pass through it unscathed. During the past season they have been much less damaged in exposed than in low-lying positions, though even there the woolly-leaved ones are almost past recovery. The plants known in gardens as *C. florentinus*, *C. lusitanicus*, and *C. cordifolius* have not been touched at all; *C. monspeliensis*, *C. Clusi*, very little; while *C. villosus* and its varieties *C. vaginatus*, *C. salviaefolius*, have been damaged almost past recovery. *Helianthemum formosum*, *H. lasianthum* and *H. ocyroides* (often and perhaps better known under the name of *Cistus*) have been all killed outright. *H. rosmarinifolium* has been badly damaged, more so than it has been with us in the neighbourhood of London during the last dozen years. *C. laurifolius* is perfectly hardy; and in the same position, in low-lying ground and sheltered, *C. populifolius* has been killed.—L.

Violas.—The most charming of the Violets, excepting, of course, *V. pedata* var. *bicolor*, for flowering at this time of year is the handsome Falkland Island species, *V. maculata*, named, I believe, on account of the black dots at the base of the leaf serratures. The flowers are deep, almost orange-yellow, larger than *V. odorata*, and borne above the foliage at least 2 inches or 2½ inches; the throat is veined purplish, radiating from the base almost to the margin. It is perfectly hardy, and does well on a sunny slope in light rich gritty soil. It is in flower now at Kew. *V. biflora* is well suited for planting in crevices on a shady wall; it grows freely without the slightest attention, and soon covers the allotted space. *V. cornuta* and *V. c. alba* are also very useful on the rockery, the latter especially, as it is extremely free and continues in flower for such a long time. *V. pyrenaica* is a good species for overhanging ledges, &c.; as also is *V. Munbyana*, which is a very free-flowering and pretty plant when grown in good rich soil. *V. pinata* is well worth having as a late flowering variety as well as *V. pyrenaica*, *V. gracilis*, and others.—K.

Hollyhocks planted out in autumn.—One of the healthiest pieces of Hollyhocks I have ever seen consists of strong seedlings that were planted out last October. No mulching of any kind was put about them, as it is considered beneficial that all the sunshine possible during the autumn and winter should play about the plants. In spring, when a quickened growth sets in, the young suckers are cut away from the main stem, because what is required

is that the plants should send up a strong stem that will produce as much seed as possible, and if the weather is dry, a good root-watering is given, and then a mulching of short manure is laid round each plant, but a few inches away from the stem all round, so that water can be given without difficulty. Very fine, clean, healthy plants are produced in this way, and very little trouble is caused by the disease. The moral of this treatment is, Give the plants a good start, and they can scarcely fail to come out well at the end.—R. D.

THE PROPHET FLOWER.

(*ARNEBIA ECHINOIDES*.)

IN reply to "R. D." in THE GARDEN of May 28, 1887 (p. 486), who asks, "Why is this called the Prophet Flower?" the legend is, that on one occasion when travelling in some desert waste the Prophet Mahomet suddenly came on this little flower, and so rejoiced was he that he laid his hands in blessing on its golden petals, leaving the print of his fingers in the five black marks; hence its name. I believe I was the means of its introduction into England, as I sent the seed from India to the late J. Anderson-Henry, who raised and forwarded it to Kew. Hindoo gardeners are most inimical to the plant as one dear to those of an opposing creed, and the friend who gave it to me said, "You will never be able to keep it; your gardener is sure to root it out;" and so indeed it proved. On my return from the hills to Rawul Pindi not a trace of it could I find. It grows wild, however, somewhere in that district. Kew also owes to me the re-introduction of the blue Poppy, which has flowered so prettily there in the rock garden the last two summers.—LOUISA C. JOHNSTONE, *Grange-wood, Border Crescent, Sydenham, S.E.*

—The fine specimen of this beautiful yellow-flowered perennial Borage, recently exhibited by Messrs. Paul and Son, Cheshunt, should lead to its more extended cultivation. "R. D." in THE GARDEN (p. 186) asks why it has received its English name. This has been derived from the legend which says that when the Prophet Mahomet first saw the bloom he was so impressed with its beauty, that he laid his hands upon it to bless it, and left the marks of his fingers upon the petals. The impression supposed to have been made vanishes as if washed away after the flowers have been open a few days. It is much to be regretted that although this plant has been introduced to this country some forty years, it is so seldom seen in our gardens. Seeds of this plant were sent from the St. Petersburg Botanic Gardens to Kew, where it flowered for the first time in this country in the summer of 1848. It is quite hardy, and is readily increased by cuttings taken in the autumn, and inserted round the sides of the pots in light sandy loam. In this state they may be placed in a cool house or frame through the winter; when spring arrives they will be found to have made roots. The young plants are best grown in pots until they are sufficiently hardy to bear planting out. Pieces of the stoutest roots also grow readily when placed in pots and subjected to a slight bottom-heat. The plant also produces seeds in favourable seasons, and therefore no reason exists for its rarity. A coloured figure of this plant was given in Vol. XVIII. of THE GARDEN (p. 201). *A. Griffithi* is another species introduced to Kew about twenty-five years ago from Northwestern India. It is not perennial, but only of annual duration; this fact, however, does not detract from its beauty, although it increases the trouble in its cultivation. It differs from *A. echioides*, moreover, in its smaller flowers and narrower leaves, but the colour is a much deeper shade of yellow and the spots are of a darker hue.—G.

—*Arnebia echioides* is called the "Prophet Flower" because the vanishing black spots were produced, according to a Mussulman's belief, by the touch of the Prophet's fingers. MAX LEICHTLIN.

Sparrows and flowers.—During the past spring sparrows have been unusually destructive in many places to the bloom not only of Primroses,

but also that of fruit and other trees, but the note from "A. D." in THE GARDEN (page 486) confirms what many others have suggested, that the damage is to a great extent owing to the protracted drought, for we have had an unusually dry, as well as cold, spring. I also believe the sparrows pick off the bloom for the tiny drop of nectar or moisture they contain, and are, therefore, far more destructive in dry seasons than when showers prevail. In this locality we have no ditches, except dry ones, for a long distance, and many owners of gardens have, during the last few weeks, taken the precaution to place saucers full of water about their gardens for the birds to drink from. Whether it may prove an effectual remedy I cannot say; but many who love their gardens are also equally fond of birds, and would like to see any remedy adopted rather than be driven to the necessity of destroying their feathered friends, as even the common sparrow is welcome when birds of other kinds are so scarce.—J. G. H.

PHLOXES.

THE genus *Phlox* is one of several which have been encumbered and have had their natural species confused by the bad habit of giving Latin botanical names to garden varieties. We might collect from the illustrations of Curtis, and Sweet, and Edwards, and other popular books on horticulture more than twice as many Latin names of *Phloxes* as there are species in the whole genus, though about half the species of the genus are not, and probably never have been, in cultivation at all.

The authors of "Genera Plantarum" agree with Asa Gray in fixing the number of species of *Phlox* at twenty-seven, all of which are indigenous to North America. Two of these are annual, one being the well-known *P. Drummondii*.

Thirteen others are dwarf suffrutescens mountain species, which it has been hardly possible to cultivate, some of them not being worth cultivation. One of them is figured in *Botanical Register*, 1351, and, pretty as it is, it was lost almost as soon as it was introduced. Another, of less merit, was recently sent to me by Mr. Paul, of Broxbourne, under the name of *P. Douglasii*.

Of the twelve remaining species, eleven belong to section No. 2 of Asa Gray's arrangement, being defined as "Perennial Herbs of the Atlantic States," and ten of the twelve are common in cultivation, the twelfth being a section by itself, and being the well-known *P. subulata*.

Three species of the first section seem to have formed the stock of the florists' *Phloxes*, viz., *P. paniculata*, *P. maculata*, and *P. glaberrima*. *P. floridana* and *P. bifida*, if in cultivation at all, are rare, and I have never met with them. *P. pilosa* flowers in summer, and is difficult to keep in wet soils. Six species remain to be enumerated, which are amongst the brightest ornaments of our spring gardens. They are:—

P. OVATA.—Not flowering till late in spring, but of very good habit; about a foot high. It should be frequently renewed from small pieces, and does well in any soil. Syn., *P. carolina*. Figured in Sweet's "Flower Garden" as *P. triflora*.

P. ARGENTEA.—By far the best of its class. Grows about 6 inches high, and produces a thick mass of bright pink flowers from the middle of April to the middle of May. It requires to be pulled to pieces and re-planted every year, as it spreads rapidly and seems to exhaust the soil. It likes light, rich soil, and a situation sheltered from cold blasts and sharp frosts, which spoil it. Still, it may be grown well in any garden in selected spots, and is unusually good this year.

P. DIVARICATA.—Habit similar to the last, but rather taller; colour of the flowers slate blue; flowering season April and May; less impatient of cold than *P. argentea*, but so liable to be devoured by slugs, that where they abound it requires guards of perforated zinc round it. It should be propagated frequently and kept in a compact mass. Syn., *P. canadensis*.

P. REPENS.—Early, bright and pretty; resembles *P. argentea*, but the leaves are larger and rounder.

and the growth more sparse and straggling. In my garden it is not nearly so free flowering as *P. amœna*, but I have seen it very good in some southern gardens. Syns., *P. stolonifera* and *P. verna*. I have a variety with smaller flowers than the type and of a dull purple colour—by no means desirable.

P. STELLARIA.—Said to be so called from its general resemblance to *Stellaria holostea* (the great Stitch-wort), which it recalls both in habit and in flower. Its early flowering gives it some merit, but it is not one of the best, and in wet soils withers in winter, or the stiff, persistent branches get broken off by wind.

P. SUBULATA.—The most useful and favourite species of all the dwarf Phloxes, and consequently the most liable to abuse by having so many other names, figuring as *P. setacea*, *P. nivalis*, *P. atropurpurea*, *P. frondosa*, &c., in the same catalogues in which other varieties of it are properly entered with florists' names. Though it varies a good deal as a wild plant, these Latin names are now excluded by botanists to avoid confusion.

There is a very old, but delicate Phlox with pale purple flowers called *P. procumbens*, said by Asa Gray to be a hybrid between *P. subulata* and *P. amœna*. I believe that there are several hybrids of this class in cultivation, and I am trying to collect them, but I can find only one figured, viz. in Sweet's "Flower Garden," series 2, tab. 7.

Edge Hall, Malpas. C. WOLLEY DOD.

The Crown Anemone ("St. Bridget's" strain).—I must differ with "J. C. C." when he says (p. 467), "When this Anemone is treated as an annual there must be no further delay in sowing the seed if intended to flower during the winter months." This Anemone is grown as a specialty in all the gardens around here chiefly as an annual. The method adopted is to use the seed from the best "marked" plants only. The plan is to mark the intended seed-pods with crimson, blue, red, &c., Berlin wool, according to colour, and remove all the pods and stems, with the exception of one or two, so as to utilise the whole force of the sap in perfecting the seeds. This is too often lost sight of, and the result is a worthless strain. This seed cannot be ripe for a few weeks yet, and consequently cannot be sown. Your correspondent may mean seed selected last year, but I do not think this so desirable. Of all the strains of Crown Anemones none can compare with the above. I have always found the best results by blooming the plants in the seedling beds—not transplanted. The plants get a check in transplanting in summer that they never fully recover from. W. J. MURPHY, *Clonmel*.

SHORT NOTES.—FLOWER.

Many-flowered Snowflake (*Leucojum trichophyllum*).—I bloomed this plant some years ago. The bulbs came from near Seville.—A. RAWSON, *Windsor, W.*

Spiræa Aruncus astilboides.—We have lately had this grand *Spiræa* in bloom, and it is one of the best. It is a free and robust grower, and blooms most profusely, the spikes being large and pure white. It merits universal culture.—J. MUIR, *Maggoo*.

Bluebells.—During the feast of Bluebells that we have been enjoying, I notice several fine pure white forms. Has anyone noticed them in quantity? I fancy a good mixture of the white and blue would be even more effective than the blue by itself.—A. H.

Primula Parryi.—This rare Rocky Mountain Primrose is now flowering in the York Nurseries. The blossoms are large, magenta-purple in colour, and are borne in clusters on stems 6 inches to 12 inches high. The plants are growing in a deep peat bed shaded by brushwood. Finer or more healthy plants we do not remember ever to have seen.—R. P.

The early Orchis (*O. mascula*).—I see Mr. Webster says "that the climate of the south of Ireland is well suited for the cultivation of this pretty, early-flowering kind."

As the plants in the greatest vigour and abundance in many districts near London, it is curious that Mr. Webster should write of this commonest and hardiest of early native Orchids as if it were a rare or semi-tropical plant wanting the climate of Cork.—E. H.

Camassias at Edinburgh.—The *Camassias*, &c., which I sent yesterday came from the botanic gardens. As grown there in large groups, the various forms of *O. esculenta* are very effective. *O. C.* Ledeburii was sent to the gardens on its first introduction by Dr. K. Brown, who collected it when on the Oregon expedition. The hybrid *Aqui-*

legia Stuarti (*glabulosa* × *Wittmannii*) is very beautiful, but I fear the flowers may have faded before they reach you.—C. M. OWEN.

INDIAN PRIMULAS.

IN the Journal of the Linnean Society for 1882 (vol. xx., No. 123) will be found a very interesting memoir on some of the undescribed and imperfectly known species of Indian *Primula* and *Androsace*, by Mr. Geo. Watts, M.B., F.L.S., of the Bengal Educational Service, Calcutta. This memoir is profusely illustrated. In the spring of last year many lots of Primrose-seeds were received from India, in connection with the work of the *Primula* Conference, and about these we have as yet heard very little. There are many Indian *Primulas* of great beauty awaiting introduction to our gardens. These already acclimatized, such as *P. cashmeriana*, *rosea*, *denticulata*, *sikkimensis*, and *capitata* are so beautiful and so hardy, that we naturally long for more.

Dr. G. King, F.L.S., of the Royal Botanic Gardens, Seebore, near Calcutta, very kindly sent me a few packets of seeds in December, 1885, "collected at high levels of the Sikkim. Some of these species," he said, "have never before been introduced into Europe." I have given much care and attention to the growing of these, and with a fair amount of success. Amongst the seeds was a packet, marked "*P. capitata* (Hooker) and *P. bellidifolia* (King) mixed." Collected above Lachong at 13,000 feet, in sunny situations. These seeds have grown well, and produced many beautiful blooms of *capitata*. There are certainly two varieties of flowers, one a much darker and richer violet colour than the other, but I am as yet unable, without an exact description, to select the new variety *bellidifolia* (Daisy-leaved) from the ordinary form of *capitata*. The plants have proved perfectly hardy, having passed through the severe winter in the open garden, and bloomed beautifully in March and April several are still in flower. I have not seen a description of this new variety, as it is not noticed in Dr. Watts' memoir.

Another package contained seeds of *P. reticulata* (Wallich) collected near Cheombi 11,000 feet, between rocks in exposed wet places. Of these we have an abundant crop. At first I took it to be the well known *P. sikkimensis*, but on applying to the Kew authorities for further information, as this variety was not described by Watts, Mr. Dewar wrote me as follows: "I quite agree with you in saying that *P. reticulata* is nearly allied to *P. sikkimensis*. The chief distinction is a larger flower-scape, fewer flowers, mouth not annulate, of a dull yellow, the leaves with very much longer petioles, and the margins double and sharply crenated." This description agrees exactly with our plants, only I should describe the leaves as doubly serrated at the edges instead of crenated, and that the reticulations were much more strongly marked, as one would expect from the name by which Wallich distinguished it. It is a finer plant than *sikkimensis*, having flowers of a richer colour, larger, and more beautiful in form. The scape is about 20 inches high, and it carries from twelve to twenty flowers, well expanded and drooping. The stalks and leaves are powdered, and the petioles red and longer than in *sikkimensis*. The calyx is more inflated, and its segments keeled, as in our English Cowslips and Oxlips, which these Indian Primroses somewhat resemble in form and habit. I consider *P. reticulata* to be the finest Indian *Primula* which has come under my notice, and that it will be a grand addition to our gardens. It is perfectly hardy, having been grown from seed and flowering without heat and in the open garden.

Brockhurst, Eidsbury. WM. BROCKLEANK.

Flowers at Shirehampton.—*Pæonies* (Montan) grown in the open are now (June 1) in their glory. A crimson single gold-edged variety, received here through Mr. Gordon direct from Japan, marked No. 15, is magnificent. I flowered about twenty single and double varieties in pots six weeks ago; one measured 23 inches round and $1\frac{1}{2}$ inches across. When these grafted *Pæonies* throw up shoots from the stock, ought the shoots to be cut off? The Montan varieties

are grafted on their own roots; these also throw up shoots. I hardly like to cut them off. *Sparaxis*, *Ranunculus*, *Ixias*, *Babianas* grown in sand and peat Moss manure have done very well in a cold frame. The early *Gladioli* (*byzantinus* and *G. albus*), with *Ixias*, *Watsonias*, and several Cape bulbs, grown in the same compost against a south wall, with a light over them through January and spring months, are looking very forward—the *Gladioli* nearly in bloom. I have some sixty plants of *Remneya Coulteri*, about 2 inches high, planted out in boxes from seed sown six weeks back, in a greenhouse. Should I leave them in the boxes or pot off? I agree with the correspondent who asks that everyone should state where they write from. I should add that it would be a great convenience if all communications were dated. The fasciation of Lilies is a great trouble here; is it caused by too close planting? I have a bed of seedling Lilies—*Martagon* and *colchicum*; the latter have become badly fasciated.—C. O. MILES, *Shirehampton, Bristol*.

Laced Auriculas. In reply to J. Douglas, in THE GARDEN (p. 185), I make no claim as to the original introduction of these laced Auriculas, but I claim to have been the first to draw attention to them by publicly exhibiting them, and still farther to attempt their improvement. When originally shown, they were not at all warmly welcomed by the rule-of-thumb Auricula men, who instituted at the Auricula shows a class for nondescript Auriculas yeleft "fancies," and permitted laced alpines to be shown in this class. The result invariably was that the nondescripts were placed before beautiful laced flowers, and the generous offer proved worthless. Now we learn that they may be exhibited in certain classes for alpines; but of course they have no chance with ordinary Auricula fanciers when put into competition with decent show, shaded, or self-alpines. It is very obvious that if the Auricula committee were less anxious to promote the cultivation of certain classes of Auriculas, and cared more to encourage all good forms, even if novel, they should do so. It is difficult to discern how beautiful a strain may yet be got from the laced section. I still am of opinion that the broad colouring of an alpine Auricula is toward the ground, and not the edging. Still, I am not infallible.—A. D.

Notes from Aix-les-Bains.—This place is now a garden of flowers—wild and garden, tree and plant—and is well worth a visit for other than curative reasons. The park is ornamented with many flowering trees and shrubs, the most noticeable being scarlet and white, single and double Chestnuts, *Paulownia imperialis*, *Magnolia conspicua* (just going out of bloom), and *M. laurifolia* (showing its buds), *Spiræas* of various kinds, *Tamarisk*, and Hawthorns well covered with bloom. In the market, wild flowers may be bought every morning; Lily of the Valley in quantities, *Gentians* (*G. verna* and *acaulis*), *Globe flower* (*Trollius europæus*), and *Orchis* in many varieties. The woods and roadsides are brightened with the Star of Bethlehem (*Ornithogalum*), and *Iris germanica* seems to flourish everywhere. I have not yet come upon it as plentiful as in Switzerland, where, in the valley leading to St. Luc and Zinal, it grows all over the hillsides; but, on the whole, this interesting and picturesque neighbourhood is quite as much a garden as is the more spoken of home of Swiss flowers. *Narcissus poeticus* I must not forget to mention finding in the market, but I have not seen it growing. I have enjoyed acres of its beauty and sweetness in the district surrounding Montreux, where it can be seen from the lake to whiten the hillsides as if with a shower of freshly-fallen snow.—J. H. P.

Sowing Stocks and Asters in the open ground.—Most of those who grow Stocks and Asters sow their seeds in a gentle heat, or on a prepared bed in a cold frame, and then prick them out in the open ground. If dry weather sets in just when the transplanting should be done, valuable time is lost, because the plants are some time in getting a start. It is this among other considerations that has induced Messrs. Sutton & Sons to sow all their Stocks and Asters for trial in the open ground. It

is true that the soil of their Portland Nursery in the London Road is of a light, sandy, and friable nature, and the position open and sunny, conditions favourable to a good growth of seed in the open air. The ground was duly prepared, and where the drills are to be drawn the ground is first of all flattened down by placing a piece of stout board along it and the men stand upon the board so as to make the soil flat and hard. Then a shallow drill is drawn, and the seeds sown thinly and covered lightly with some finely sifted old potting soil. When the plants are large enough they are thinned out to a foot apart, and those taken from the ground are planted out in borders, &c. It is found by experience that the plants that have not been disturbed from the time of sowing, root themselves deeper into the soil than transplanted ones; they grow finer and give flowers of a better and more lasting character, and they bloom earlier. Sowing is done about the 12th of April, but it must not be supposed that sowing in the open air can be safely done in all localities and all soils. It is only under such favourable conditions as exist at Reading that outdoor sowings are so successful. Of the many hundreds of samples, not one appears to have failed. If wireworm attacks the plants, the best cure is found to be a sprinkling of wood ashes strewn lightly over the plants.—R. D.

CHRYSANTHEMUMS.

E. MOLYNEUX.

CUTTING DOWN THE PLANTS.

FOR ordinary conservatory decoration, where large blooms are not wished for, the method of growing the plants for producing large flowers is not the one best suited for obtaining plants fit for grouping in the majority of conservatories. Plants for conservatory use must be strong in the growth, dwarf in habit, possess ample leafage, and be capable of bearing handsome blooms which can be seen without the use of the step-ladder. Flowers produced on such plants as these are generally admired while growing upon the plants; whereas the large flowers grown on the ordinary exhibition method are generally seen when cut and placed upon the boards either ready for or at the exhibitions. In such a case as this, tallness of the plants is only a secondary consideration as regards appearance, it being a generally recognised fact that to produce the finest quality of flowers the plants must grow high, and assume somewhat of the natural habit of growth of each distinct kind. As varieties differ so much in character of growth, there is, of course, a wide range to choose from. Some kinds naturally do not grow above 3 feet high, while in some seasons other sorts will attain the enormous height of 12 feet. Of course this occurs where a limited number of flowers is allowed upon each plant, and where the object is solely the exhibition table; such quality cannot be produced upon plants which are rendered dwarf by special treatment. These dwarf plants will produce flowers large in diameter, but they invariably lack that depth which is so essential in the finest blossoms. For the production of dwarf plants suitable for conservatory decoration a special course of treatment must be adopted. The plants being mainly used for grouping, they are generally stood close together when in bloom; therefore the pots used for the final shift should not be more than 9 inches across. It is better that all should be of one uniform size, as arranging the plants in a satisfactory manner is more easily accomplished.

The cuttings will have been struck at the usual time and the plants grown on as for other purposes, with one single stem, up to the present date. If plants have not been specially set apart for this object, any surplus ones over the number required to produce exhibition blooms

will answer the purpose. Should these be the naturally late-flowering kinds, such as Boule d'Or, Meg Merrilies, Yellow Dragon, Grandiflorum, Princess Teck, Hero of Stoke Newington, and Cherub, cutting down should commence at once. Varieties which flower in an ordinary way about mid-season without any special treatment, as, for instance, the Queen family, Princess of Wales, Jeanne d'Arc, John Salter, Jardines Plantes, and Baron Beust; and among the Japanese, such varieties as Madame Audiguier, Fair Maid of Guernsey, Baron de Prailly, Mdle. Lacroix, Peter the Great and M. Astorg should be cut down about the 1st of June. Those two richly coloured varieties, Cullingfordi and King of Crimson, the best of the reflexed section, almost indispensable in a group owing to their brilliant colour, come under the last-named list. Early-flowering sorts, to wit, Elaine, Prince Alfred, Lord Wolseley, and the Rundle family, should not be cut down before the middle of June. None should be cut down later than the middle of June if they are required to be in bloom from the early part to the middle of November. It is well to take into consideration the purpose for which the plants are required, whether for large or small groups, in determining the height at which they are to be cut. Always select for the front of the group those kinds which are naturally dwarf; as a rule, they possess the best foliage, being short-jointed; thus the leaves overlap each other, which is a decided gain in the end, as the front part of a group in particular is much influenced in its appearance by the general foliage of the plants. Where groups of this class are placed in competition with others, the condition of the foliage has considerable weight; therefore, every means should be taken to gain this end.

Dwarf-growing varieties best suited for front rows of groups may be cut down to within about 4 inches of the soil; the others to 6 inches, 8 inches, and 12 inches, as they do not break so freely from the old wood as from the young plants. Small-flowered varieties, which are intended to have more branches, should not be cut so low as varieties with larger flowers. After being cut down the plants do not require much water at the roots for some time. If they could have the protection of a cold frame for a time, so much the better. Syringe the plants once a day, to assist the shoots starting into growth, from the eyes below where the top of the plant was severed. As soon as the shoots are long enough to determine if they are perfect and the leading points not deformed, disbud to the number required; three branches suffice for most large-flowered kinds, but the small-flowering sorts may have six each. When the new growths are well started, transfer the plants to their flowering pots, those they now occupy being 5½ inches across. When the roots have run freely into the new soil, remove the plants to their summer quarters, allowing them ample space, as crowding the plants together quickly spoils their appearance, drawing them up weakly and ruining the foliage. At this stage of growth the shoots are easily snapped at their base by winds and other circumstances, such as birds alighting upon them. Tie each branch securely to separate stakes, and as soon as the pots are filled with roots, stimulants may be applied. The first buds produced on the shoots after cutting down should in nearly all cases be selected as best suited for producing large blooms. They will appear from the middle to the end of August, and it will be soon enough if some sorts, such as the Queen family, show their buds the first week in September. Sometimes a bud of the latter varieties, for instance, will show itself during the first week in August, in which case

rub it out and wait until the next one appears, which will be about the middle of September. When this occurs, the plants will be a little taller than they would otherwise when the flower-buds show at the proper time. Such plants being taller are better suited for the back parts of the groups. When the flower-buds are selected, take out all growth-shoots around the bud, as the formation of the bud induces a number of shoots to form. The growths from the sides of the plants will all have been removed as fast as they have appeared, to throw all the strength into the leading stems.

Commence to house the plants if the weather is dull or cold about the last week in September, commencing with late-flowering varieties, such as Boule d'Or, Meg Merrilies, and Hero of Stoke Newington, for instance. These varieties require a longer period to develop their blooms than the majority of the sorts; therefore more time should be allowed them, as they come out quicker under glass than outside. Local circumstances must be taken into consideration, as early frosts are more prevalent in some localities than others. The plants should be under cover before these take place, or the flower-buds may receive a check. Early flowering kinds may remain out of doors until the middle of October, which retards the opening of the flowers somewhat. Place the plants as near the glass as possible, giving sufficient space to each to prevent loss of foliage. Fire heat will be needed occasionally in dull weather to prevent the blooms damping and mildew from spreading. A close watch should be kept upon this fungus the moment any signs of the pest appears, and as a remedy dust the affected parts with sulphur.

GARDEN FLORA.

PLATE 600.

HUNNEMANNIA FUMARIEFOLIA.*

THIS most beautiful and graceful foliaged member of the family of the Papaveraceæ which is closely allied to the *Mecomopsis* section is a native of Mexico, whence it was first introduced to European gardens by means of seed about sixty years ago by Mr. Robert Barclay, from whose garden at Bury Hill flowering specimens were sent in the year 1829 to Mr. Sweet, who figures it on plate 276 of the third volume of his "British Flower Garden." It is also figured on plate 3061 of the 58th volume of the *Botanical Magazine*. This pretty plant, though flowering best in the open sunny border, must be treated as a half-hardy biennial, and be continually renewed by seed, which it happily sets and ripens freely even in cold and sunless summers, such as ours was last year. I sowed the seed as soon as it was ripe, and it lay dormant for nearly six months, beginning to come up about the first week in March in a cold house where the seedlings are still appearing. The charming glaucous hue of the deeply-cut foliage forms a beautiful contrast to the clear and brilliant shade of yellow of the flowers. Both are most accurately portrayed on the accompanying plate. W. E. GUMBLETON.

Notes from Baden-Baden.—*Eremurus robustus* var. *nobilis* is a splendid variety, and far superior to the best typical form; the flowers are larger, deeper in colour, and the spike much bigger; it is a month earlier than all other forms. Among Irises, *I. coreana* is a very showy plant, the deep bright ultramarine flowers being produced in the

* Drawn by Miss Travers in Mr. Gumbleton's garden, at Belgrove, Queenstown, August, 1886, and printed by G. Severeys.

HUMMELINA PINNATIFOLIA

greatest profusion. *I. Troyana* of the germanica section, with sky-blue standards and brilliant violet falls, is a lovely, sweet-scented flower. *I. asiatica*, a variety with rich violet flowers, is the largest flowered Iris I know of. *I. Kochi* is a most profuse flowering one, colour deepest violet; contrasting well with this is *I. albicans* from Cyprus, a pure white sweet-scented sort. A very interesting Allium is *A. Rosenbachianum*, with very large heads of purplish flowers, though it is not so showy as *A. giganteum* and *nobile*.—MAX LEICHTLIN.

ORCHIDS.

W. H. GOWER.

SACCOLABIUM GUTTATUM.

THIS plant is considered by Professor Reichenbach to be a variety only of *S. retusum*; it is, however, sufficiently distinct to be readily distinguished from that plant when in flower, whilst even by its growth alone it can be recognised from it by those well acquainted with the genus. The section of *Saccolabium* to which *guttatum* belongs all produce long cylindrical racemes of bloom, the flowers, although small, being exceedingly beautiful. In this plant they

Saccolabium guttatum.

are thick and fleshy in texture; sepals and petals waxy white, freckled and dotted with rosy purple, the colour being more or less intense in different plants; lip small, wholly deep purple. In habit of growth the *Saccolabium* are characterised by their thick, fleshy, leathery leaves, which are præmorse at the ends, and arranged in a two-ranked manner. With age *Saccolabium guttatum* produces lateral growths, and when it attains to the dimensions represented in the accompanying engraving, its beauty cannot be adequately described.

SACCOLABIUM GUTTATUM is a plant slow in growth, and therefore care must be exercised in its cultivation, so that every leaf may be preserved. To this end it will be found more advantageous to lower the temperature during the winter months, withholding the water supply to a great extent, than to subject the plants to the high temperature and the dry atmosphere to which they are subjected naturally during the resting season.

S. GUTTATUM HOLFORDIANUM is a plant of a more robust habit of growth than the typical plant; its wreath-like, cylindrical racemes of bloom are also much stronger and longer, whilst

the colours are richer, the lip being bright crimson. Both forms are natives of India and some of the Indian Islands.

During the growing season this plant enjoys the strong heat and moist atmosphere of an East India house and an abundance of light, but it requires to be shaded from the fierce rays of the midday sun. Small plants of this species thrive well enough fastened to a block of wood with a little *Sphagnum Moss* to retain moisture about it, but as they increase in size they become massive and weighty, which renders it necessary to place them in baskets, which should be suspended near the glass. *Saccolabium guttatum* is sometimes grown in pots with *Sphagnum Moss*, but the thick, fleshy roots enjoy being free, in which manner they can absorb the moisture of the atmosphere, and therefore basket culture is preferable.

Dendrochilum (Platyelinis) latifolium, in flower at Messrs. Veitch's, is quite a handsome species with spikes of flowers, 9 inches in length. They have the sweet perfume of *D. glumaceum*, but with much larger flowers; it is a very desirable species, and flowering, as it does, before *D. filiforme*, it is of greater value. The *Dendrochilum* are not

very plentiful in collections, but they are very lovely, and the sweet perfume of some of them adds immensely to their value. *D. filiforme*, when it has grown to a large size, is an excellent exhibition plant, and forms a distinct and attractive specimen amongst other more formal-looking subjects. I have found it do well both in the *Cattleya* and East India houses.—J. D.

Dendrobium speciosum.—Many growers fail to flower the above Orchid satisfactorily, and at one time my treatment of the plant was a mistake and resulted similarly. I discovered a more successful method quite by chance. Some years ago some alterations in the forcing houses were commenced in September, and I had to store a lot of my plants away in pits that were only heated sufficiently to keep out frost, and amongst them were two large plants of this *Dendrobium*. They remained there until the following March, during which time the plants had very little water, sometimes going without for a month at a time. They stood upon pots at the back of the pit and had plenty of light and sun, also plenty of air when it was convenient to open the lights. When the houses were finished, these plants, with others, were taken into an early vinery, and after being top-dressed with good peat and *Sphagnum*, were well watered and placed on the stage over the pipes. This sudden change of

treatment appeared to be the right thing, for in due time the buds at the top of the pseudo-bulbs began to move as if for flowering, which proved to be true, for one plant produced eleven spikes and the other one nine. This unlooked-for success proved that I had hitherto been treating the plants too liberally by always keeping them growing, and for a great part of the time in too high a temperature, and never giving them a sufficient rest to ripen or mature the buds. I have ever since submitted this Orchid to those conditions of treatment, and have not failed to flower it regularly.—THOMAS RECORD, *Falkington Manor*.

FLOWERING ORCHIDS AT HAMMERSMITH.

WHEREVER hardy plants will grow, we strenuously advocate their culture before any other class, but where gardens or grounds are so situated that the surroundings are not congenial to the well-being of herbaceous or alpine plants, it is quite useless to make the attempt. Grounds of this character exist in the immediate suburbs of London, and Mr. Tautz at Hammersmith, recognising this fact, has wisely covered the greater portion of his garden with glass and made the culture of Orchids his special study. These houses all the year round are gay with bloom, and at the present time are more than usually so. All the plants are in rude health, and the houses are cool and pleasant. Amongst the most notable plants in flower just now is *Odontoglossum vexillarium*, some 500 or 600 blooms being fully expanded, whilst the numerous buds opening and others still developing give reasonable promise of as many more, which will continue the show for several weeks. Mr. Cowley says, "I never syringe the *vexillariums*, and I grow them cooler than many do; they are kept in a temperature somewhat midway between that of the *Odontoglossum* house and an ordinary *Cattleya* house;" and certainly the plants appear to thrive in a marvellous manner under these conditions. Besides these, between 100 and 200 varieties of Orchids are now displaying their beauties, amongst which may be seen some richly coloured forms of *C. Mossia*, the variety named *purpurata* being very conspicuous. The flowers of this are deep lilac in the sepals and petals, whilst the large lip is wholly deep purplish crimson, with a full orange throat, the edge being white and prettily crisp. Numerous forms of *C. Mendeli* are also now coming in; one in particular is notable, and deserves a varietal name. It has the appearance of being crossed with *Laelia elegans*; the sepals and petals are pure white, whilst the lip in shape somewhat resembles the variety of *L. elegans* known as *Wolstenholmie*. It is white, stained in front with purplish lilac. Amongst other *Cattleyas* specially good are well-flowered specimens of the rare *C. Skinneri oculata*, *C. Schrederi alba*, which yields a delightful perfume resembling sweet vernal Grass (*Anthoxanthum odoratum*); *C. Lawrenceæ*, *C. Aclandiæ*, *Laelia grandis*, *L. purpurata* in quantity, &c. These plants are never syringed, and are kept cooler than *Cattleyas* usually are. *Lady's Slipper Orchids (Cypripediums)* are largely grown here, a recent addition being *C. Laforcade*, a hybrid raised by Messrs. Veitch. It is distinct and very beautiful; the dorsal sepal is large, flaked with fiery reddish purple and bordered with white; petals plain dull purple; lip small and pointed, resembling *C. niveum* in shape. Here also are blooming fine examples of *C. Peteri*, *ciliolare*, *Swaniamum*, *callosum*, *Lowi*, *Lawrenceanum*, *caudatum*, the rare white form of *Sedeni* called *candidulum*, a deep yellow form of *Druryi*, the bright-flowered and perpetual blooming *C. Warneri*, a highly coloured form of *C. Hookeri*, *C. Boxalli*, *C. Harrisianum*, &c. The collection of these *Cypripediums* is very extensive and the specimens remarkably healthy, growing in the temperature of an intermediate house. The coolest house devoted to *Odontoglossums* and the mountain *Oncidium* is bristling with innumerable spikes, which promise a continuation of bloom for months to come. Amongst the most notable were good plants of the white and the rose-coloured *O. citrosimum*, and a very pretty form called *punctatissimum*, in which the sepals and petals are profusely dotted with rose. *O. ramosissimum* is a species

rarely seen; it has a densely-flowered branching spike of bloom, which in shape somewhat resembles *O. nevium*; sepals and petals creamy white dotted with lilac, and a lilac lip. *O. Reichenheimi*, bearing a large, much-branched spike; *O. Schillerianum*, distinct from any other species; dark and light forms of *O. triumphans*; white and spotted forms of *Alexandre*, and *Pescatorei*, *nebulosum*, *candidulum*, and many others. Associated with these delicate flowers are numerous richly coloured forms of *Masdevallia Harryana* and *Epidendrum vitellinum majus*, *Oncidium concolor* and *O. cucullatum*. *Phalenopsis*s, when in flower, are moved from the growing house into that occupied by the *Cypripedium*s; those now blooming are *P. amabilis*, amongst which are some excellent forms; *P. rosea* and *P. Sanderiana*, one variety in particular being of a rich deep rosy pink. The *Sobralias* are also well done here, a notable form of *macrantha* being now in flower; it is dwarf in habit, and from the top of its slender reed-like stem it produces immense flowers of rare substance of a rich rosy purple, the large lip being pure white in the basal part, whilst the sepals and petals are of the same deep colour as the lip with a light edge. *Epidendrum Parkinsonianum* is another fine plant too rarely seen; it has flat, fleshy, pendulous leaves, and large, peculiar-shaped, ivory-white flowers; two forms are now flowering here. *Dendrobium Veitchianum*, although not showy, is a very singular North Australian Orchid, the flowers being yellowish green, the lip streaked with radiating lines of dull purple. In the intermediate house are blooming good examples of *Oncidium ampliatum majus*, *O. Marshallianum*, and *O. stelligerum*, grand specimens of *Cymbidium Lowianum*, *Calanthe veratrifolia* and *masuca*, *Cologyne Massangeana*, *Colax jugosus*, and many other sorts. *Phalenopsis*s when growing are suspended from the roof of a stove in which a general collection of stove plants is cultivated, and the way in which they are rooting and the fine leaves they are making fully prove how congenial the atmosphere is to them. The plants with which the *Phalenopsis*s are associated is a varied collection of *Marantas*, *Nepenthes* with pitchers in profusion, *Anthurium*s, flowering *Clerodendrons*, the beautiful *Impatiens Hawkeri* in flower, and numerous other kinds. The Surinam *Oncidium Lanceanum* is also grown in this stove, suspended from the roof in a quiet corner, and appears to thrive admirably, as also does *Dendrobium superbiens* and various other *Dendrobies*.

Mr. Tautz is also experimenting with Orchids in the open air; these are suspended from the lower limbs of the small trees upon the lawn; amongst these we noted *Oncidium Marshallianum*, *Forbesi*, and *dasytle*, *Odontoglossum Cervantesi*, and *Cattleya citrina*, whilst *Lælia majalis*, *autumnalis*, and other Mexican kinds are more fully exposed to the sun. These plants are growing and sending out new roots, but they have not been subjected to this treatment sufficiently long to enable an opinion to be passed upon the system, or the probabilities of its success. G.

SHORT NOTES.—ORCHIDS.

***Phalenopsis sumatrana*.**—This is in bloom at Kew; the flowers are abt 2½ inches across, and richly blotched with chestnut on a yellowish ground. It is one of the most distinct of the genus, and as yet a rarity. —E.

***Odontoglossum citrosum*.**—A well-grown specimen of this lovely Orchid is in bloom at Kew. It bears two of its pendulous racemes; the flowers are 2 inches across, of neat appearance, and in colour white, faintly tinged with violet. —E.

Orchid flowers.—With this I send you a spike of *Lælia purpurata*, which we think is very fine; *Cologyne Massangeana* with twenty-four flowers on spike; *Cologyne speciosa* Lobbi, now flowering freely with us; *Cypripedium Domini*, cut from plant with eight spikes; *Odontoglossum tripudians oculata*, and a *Cattleya Trianae* just opened.—H. SIMPKINS, *The Gardens, Cambridge Lodge, Floddon Road, Camberwell.*

*. The spike of flowers of *Lælia purpurata* is very handsome, the colouring of the lip being intensely dark, but we think the sepals and petals

rather narrow; *Cologyne Massangeana* is very fine; so also is *C. speciosa* Lobbi, larger and richer in colour than the typical plant. *Dominy's* *Lady's Slipper* is good, and the variety of *Odontoglossum tripudians* is excellent. The flower of *Cattleya Trianae* represents a very handsome variety, but it is a peculiar season for this species to bloom.—E.

New hybrid *Phalenopsis*.—There is at the present time in flower in Messrs. Veitch's nursery, King's Road, Chelsea, a quite distinct form of the Moth Orchid. It has been raised from seeds in the nursery by crossing *P. grandiflora* with pollen from *P. violacea*, and it combines in a singular manner the characteristics of both parents. The plant has four leaves, 4½ inches by 2½ inches, in form like those of *P. grandiflora*. The flowers are about 8 inches in circumference, the sepals and petals cream-coloured, flushed and spotted with violet-purple at the base. The base of the labellum is a deep violet-purple with a reddish orange crest. A pair of wings rise from the sides of the labellum of a purplish colour. Those wings are not present in *P. violacea*, but are very prominent in *P. grandiflora*, only they are white and yellow in that species. In many respects the flowers take after the pollen parent. It has not yet been named. J. D.

White-flowered form of the early purple Orchid (*Orchis mascula*).—By far the finest specimens—there are four or five of this extremely rare and beautiful Orchid—that I have yet seen were pointed out to me by Miss Hughes in her richly-planted and well-wooded grounds at Bryn-y-Menai. Some of the spikes were fully 6 inches in length and composed of about thirty flowers, these being of an almost pure white, or slightly tinged with green. They had a most distinct and imposing appearance, and afforded quite a rich contrast to the deep purple of the typical plant. But not only in the cultivation of this species has Miss Hughes been wonderfully successful, for in an old scrub Oak wood hard by where the latter grows we saw the common Butterfly Orchid (*Habenaria bifolia*) quite established and throwing up fine stout spikes of flowers. Both have been growing there for some years, and seen from their robust, healthy appearance, to be quite as much at home in their new habitat as we have ever seen them on their native hillsides. I have no doubt but that our native Orchids may be more successfully grown in a grassy, open wood than in a prepared bed.—A. D. WEBSTER.

FRUIT GARDEN.

W. COLEMAN.

FRUIT STORES.

ONCE more we have an encouraging promise of heavy crops of hardy fruits, trees of all kinds having been literally covered with fine bold blossoms, much retarded, it is true, but certainly not injured by late frosts. Stone and bush fruits, no doubt, will be abundant, but these go into direct consumption as soon as ripe or gathered. Not so our Apples and Pears, which not only may be kept, but improve in quality and value by being kept for a considerable time after they are detached from the trees. This simple operation of picking and storing Apples in October surely should not be a difficult matter; neither is it, where suitable storage accommodation has been provided. In gardens belonging to the owners of the domain a fruit-room of some kind, good, bad, or indifferent, capable of holding a few bushels of Apples, is invariably met with; and the private grower in many of these is often obliged to resort to all sorts of methods for keeping out frost and snow in winter, and heat and drought in the spring. In some few gardens, excellent stores, built upon scientific principles, are met with, but amongst the rich even they are the exception, certainly not the rule. Amongst the tenantry—the masses who are now turning away

from the cultivation of grain or wasting their time in seeking protection, the men we are urging to compete with colonists living thousands of miles away—what do we find? Why, in some few farmsteads a decent Apple room has been provided; in more the look-a-head grower has fitted one up for himself; in the majority a few bushels are carried up into a garret for the use of the family. In the orchards, from October nearly up to Christmas, matters are not more encouraging. Apples by cartloads, by tons, ruthlessly shaken from the trees, are lying in heaps, covered, perhaps, with a little straw. Many of these, it is only fair to admit, are vintage sorts; but in this county alone hundreds of tons fit for human food are allowed to mangle with them, and often rot into the earth, because the growers have neither the energy nor the convenience for storing until such time as the demand will make it worth their while to send them to market. Fruiterers' shops at the present time are filled with American Apples; but why is this? Why are our own sorts conspicuous by their absence? Fruit plantations cover many thousands of acres. Fruit growing is more promising than farming; our climate, barring spring frosts, is right; we have excellent varieties, and numerous intelligent cultivators are constantly, almost daily, proving that Apples can be kept for months after the period of use formerly allocated to them. Only a few weeks ago fine collections of well-kept Apples were shown at Chester. Quite recently Messrs. Cheal and Sons sent a valuable assortment to a metropolitan exhibition, and many growers, no doubt, at the same time held small samples in sound condition. So far good; no one can deny the fact that Apples of the best quality can be grown and kept in marketable condition until the month of May. No one can gainsay the assertion that planting is now being pushed on with unprecedented vigour, as several of our largest nurserymen had sold out their best stocks months ago. A stir at the right end has induced owners and occupiers to plant, to graft, to drain, and to renovate, and all these movements mean increased production; but what benefit will the fruit farmer reap if fruit from the new plantations is to be wasted, converted into demoralising cider, or forced into glutted markets for want of store room. Early sorts which will not keep fill the London markets, and sound sorts, of which we want hundreds of thousands of bushels, if we are to make a mark, must be forthcoming. What the few can do the majority can accomplish, but no time must be lost: life is short, and in a few months hence our orchard produce will be fit for storing. Storing, forsooth! but where is it to be stored? In this county we have 27,000 acres of orcharding, and I much question if we have the convenience for storing ten bushels of Apples to an acre. How, then, are we to compete with the colonists? Whose business is it to set this matter right? Why, unquestionably, the erection of plain, substantial permanent buildings should be performed by the landlord, even if the tenant pays interest on the outlay. The wealthy may build and fit up ornate fruit rooms, but in these Apples will not keep better than in dry, thatched cellars, from which heat and cold alike are excluded and vicissitudes of temperature can be prevented. In many places large roomy stores might be made by excavating from the level at one end into dry, naturally drained banks; in others, plain brick or stone buildings with hollow walls or match-board linings would be necessary, thatch in preference to slates or tiles, as a matter of course, being employed for roofing purposes. The ways and means and modes of structure, however, it is hardly neces-

sary for me to discuss, as the thousands of practical gardeners now living in every part of the United Kingdom, ever ready to impart information, would willingly throw in their assistance. If we visit so-called international shows we see exhibited horticultural buildings and appliances of every kind and shape, practical and impractical, but fruit rooms hitherto have been neglected. If we visit the Bath and West of England and other agricultural shows, we find dairy work upon scientific principles in full swing. The best method of storing and preserving Apples I maintain is of equal importance, not only to the grower, but to the consumer, and for this reason every bushel of fruit that will keep until after the turn of the year should be hand-picked and put away to swell the bulk when colonial competition sets in.

We still have the summer before us; Nature is performing her part; we must not neglect ours; and the sooner we set about converting and constructing, the better will be our prospects for another year.

W. C.

LATE-KEEPING APPLES.

MESSRS. CHEAL AND SON, in their interesting account of their Apple store and remarks upon the late keeping of Apples, have fairly answered "R.'s" criticisms. If Apples, even of early kinds, can be kept literally restful in an even, cool temperature all the winter, they should be found hardly less excellent when eaten than at Christmas. If appearances are so deceitful, how about the gaudy coloured American samples found in our shops in the spring? But no one desires to see the very earliest ripening Apples kept through a long winter. There are plenty of kinds which do not mature till the end of October, and if fully matured, carefully selected, and stored, as shown by the Messrs. Cheal, should be little less crisp or juicy in April than at Christmas. The collections to which special reference was made recently were less remarkable for the colour of their skins than for their firmness and unquestionable freshness, and no one who saw them, so far as I could ascertain, ventured to doubt the excellent quality or the undoubted merit of the method of preservation. There seems such certainty of our having this year a very heavy crop of Apples, that it would be well if many likely to have an abundance of fruits would select good late samples and test diverse methods of keeping them, not merely with a view to preserve their freshness, but also quality and flavour. Many gardeners could perhaps spare for that purpose a peck or so of fruits of a dozen kinds. Would that someone would offer a few good prizes for the best kept six dishes of Apples, the competition to take place at the end of April next. Very likely it would encourage numerous attempts at late keeping.—A. D.

At page 491, "R." seems to ridicule the idea of keeping early and mid-season Apples until spring, saying that if they have lost their brisk flavour they are valueless. Surely he does not mean to say that if these can be exhibited in good condition, even to the eye, in spring, that it will need any great precautions to keep really late sorts as long as it is of any use keeping them. We can grow the best Apples in the world, but we rush them into market—early, mid-season, and late keepers all go together, and one frequently sees Apples, that if stored until spring would be worth 10s. per bushel, being hawked about on costermongers' carts and barrows in the autumn at about one quarter their proper value. As Messrs. Cheal remark, it is not necessary to have expensive structures for storing Apples in bulk; all that is needed is to keep them dry and cool, and free from the sudden fluctuations of temperature. It would be folly to try to keep even the latest until summer, for after Rhubarb gets plentiful, the demand for culinary Apples slackens, and when green Gooseberries get cheap it is time the old crop of Apples was sold out. But to let our late-keeping Apples be sold out by Christmas is surely not one of the things to help English

fruit growers out of their difficulties. If we can grow good Apples, we surely ought to be able to store them safely.—J. G. H.

* * * We have frequently tested the standard autumn and winter English Apples when kept late and as frequently been disappointed with their quality. Improve modes of keeping as much as possible, but there is a greater want still, and that is, first-rate late-keeping kinds. If such exist, they should be more largely planted. Do they exist? Will any Apple grower tell us what Apples of first quality yield their full, brisk, natural flavour in April? It is easy to keep Apples in good external condition without preserving their true flavour. Claygate Pearmain eaten in season and in April are two quite different things. We want first-rate late-keeping Apples. We have too many early winter kinds, and raisers go on adding to them. If people who write about late Apples do not attach any importance to flavour, good cooks are apt to put it to the test, and so are those who are asked to eat the Apples raw.—Ed.

FORCING STRAWBERRIES.

YEARS ago when I was a beginner, and even at the present time, no less size than a 6-inch pot, and in some instances 8-inch pots were used for growing Strawberries. I have for years given up the large pots and now use none larger than 5-inch, and find that I am a gainer thereby. The advice so often given that runners should be taken early still holds good, for they can scarcely be taken too early, and that the pots should be full of roots and the crowns well matured before the resting period is also sound advice. As these are the two principal elements of success in after treatment, I maintain that as the plants have but a short time in which to do their work, these conditions can be with much more certainty ensured in small pots than in large ones. I have found that the crop is no better if so good, and the fruit no finer in large pots than in small ones, and, moreover, the percentage of blanks or non-bloomers is much greater in large than in small pots. And again, large pots induce the plants to produce double or triple crowns, a thing I do not like to see, because that is generally going on when the plants should be ripening their crowns; consequently they are imperfectly matured, and when in the forcing house a superabundance of foliage and runners is the result, and very little bloom in comparison, besides taking up so much room unprofitably. I am willing to admit that plants in large pots are an advantage, as they do not need water so often as those in small ones, but as the plants require looking to once if not twice a day, the advantage secured in time is not so great after all. Some growers assert that plants in small pots are more liable to the attacks of red spider than those in large pots, and suffer more and sooner in consequence, which is to some extent true, but this is an enemy which must be fought against. By copious syringing before the plants come into bloom and plenty of moisture in the house afterwards, this is by most growers kept at bay. Now as to the difference of room taken up by the two sizes, it will be found that for every score of 6-inch pots twenty-five 5-inch pots can be comfortably put into the same space, and if the quantity of fruit on each plant is the same in both cases, the advantage clearly points to the use of small pots, and where large quantities are forced the advantage is still more apparent.

Folkington Manor.

THOMAS RECORD.

SHORT NOTES.—FRUIT.

Curl in the leaves of Peach and Nectarine trees.—Will any reader of THE GARDEN kindly say what causes the above, and also recommend a plan for treating trees so affected?—C. B.

Grape Golden Queen.—This has proved itself a wonderfully hardy Grape, bearing the roughest treatment when other varieties have given way, at the same time producing yearly a good crop of fine fruit, large in berry, well colored, and devoid of that dullness one often sees, at the same time keeping from July to November, as they did last year.—G. BOLDS, *H. p. in Garden.*

Prizes for preserved fruits.—I notice that in the schedule of prizes of the Harpenden Horticultural Society, the annual exhibition of which takes place on August 24, there is one class for six bottles of preserved fruit. This is a novel and praiseworthy idea, but I notice that nothing is

stated as to whether the fruits so preserved are of the current year or of 1886. I think the test would be a much better one if it was stipulated that the fruit must be of 1886 growth.—R. D.

Tomatoes.—In answer to the inquiry by "G. A. S." in THE GARDEN (p. 492) as to what may be considered the average weight of crop per plant from the large red variety of Tomato, I have already gathered on an average 3 lbs. of fruit from a long row of pot plants, and there is yet another pound of unripe fruit on each plant. These plants, growing either singly in 10-inch pots or in pairs in 12-inch pots, were stopped beyond the third cluster of fruit, and have received liberal treatment from the first. This weight, viz., 1 lbs. per plant, I consider a good average, especially so early in the season, but if they were planted out and allowed more head room heavier crops should be taken. The bulk of our fruit was marketed, and in a provincial town realised 1s. 6d. per lb. None will be sold for less than 1s. per lb.—I. M.

Strawberries in beds.—There is a good deal to be said in favour of growing Strawberries in beds, as alluded to by "Hortus" in THE GARDEN (p. 492), for in these days, when the calls on a gardener are so numerous, it is wholly impossible in places that are deficient in labour to get everything done at the right time. It is far better to make sure of a full crop of medium-sized fruits than to go in for those of exhibition size, and fail to carry out all the details. I have been often surprised not only at the quantity, but the quality and size of fruit of Strawberries grown on this system, or, what I suppose some would call, want of system, and have a vivid recollection of one of the old school of gardeners in Kent, who always had such an abundance of fruit on his Strawberry beds that there was really no space for weeds to grow, so thick were the plants, and as to mulching, they did not require it, for the fruit could not get splashed by loose soil, as none was visible. A good dressing in winter was all they got. Anyone having heavy demands to meet for culinary and preserving fruit, even in places where the finest dessert fruits are required, cannot do better than supplement their stock of single crowns by a few beds of thickly grown plants, as these one-year-old crowns never fail to flower freely. I have on many occasions been struck with the produce of a small plot of runners dibbled in thickly in autumn when clearing the beds. No matter how late or small, they always pushed up vigorous flower-spikes and carried good crops.—J. G. H.

SEASONABLE WORK AMONG FRUITS.

PINES.

As many of the early-started Queens will now be ripening, arrangements should be made for their removal to a warm, but somewhat drier structure in which they will finish off and keep for some time after they are ripe. A light, early viney, from which the crop is now being gathered, is an excellent place for this purpose, as the air and warmth will improve the flavour, whilst the indirect sunlight will perfect the colour of the fruit. If stock is scarce and the suckers are likely to suffer, they may be detached and potted as soon as the plants are taken out, and at once plunged in a sharp, moist heat, where possibly they will be well rooted by the time their parents are relieved of their fruit. In the general fruiting house, from which the finest Pines will be obtained, the temperature may now range from 70° by night to 80° or 85° by day and 90° to 95° after closing, with sun heat and plenty of atmospheric moisture. If the bottom heat, as sometimes happens after the firing is slackened, shows signs of declining below 80°, an effort must be made to restore it without disturbing the plants. This may be accomplished by giving the plunging bed a moderate supply of hot water and packing the material firmly about the pots, or, this being insufficient, a good layer of fresh fermenting tan or leaves placed on the surface will most likely produce the desired effect without jeopardising the crotch roots. As days increase in length and the sun gains power the watering of the plants will be

more frequent, and warm, clarified liquid, weak guano, or soot water, whilst the fruit is swelling, may be used at every watering. The latter also may be used for damping the surface of the bed and feeding the stem-roots formed in the axils of the lower leaves. The watering of Pines, it must be borne in mind, is a matter requiring great care and judgment; therefore the young beginner should always ascertain that each plant actually requires water before he supplies it. Then the watering should be thorough, but on no account should dribblers be given to keep water away. Assuming, then, that the barrel is taken round, say once a week, every plant must have a full supply or none, as it is much easier to make these slow-perspiring subjects too wet than to restore them to a healthy growing condition.

Succession plants.—The weather, hitherto so ungenial, has prevented cautious cultivators from proceeding with the transfer of young plants into their fruiting pots; but, provided all necessary preliminaries have been gone through and the compost is dry and warm, advantage should be taken of the first change to mild, gleamy days for carrying out this important operation. If, owing to the delay, the pots are extra full of roots, the plants must be carefully watered to ensure a moist-growing condition by the time they are transferred to others of larger size, otherwise premature fruiting may speedily follow. Free varieties that have filled 6-inch and 8-inch pots with roots may be shifted into 10-inch and 12-inch pots, whilst others that are not ready must be turned back, as premature potting cannot be too strongly deprecated. First-rate Pine soil cannot always be met with, but where it does abound the best fruit is generally grown without much trouble, whilst soils which require all sorts of correctives rarely turn out highly satisfactory. The main staple is turf of a sustaining nature that will hold its fibre for a twelvemonth, but where this is not forthcoming the roughest part of burnt earth, charcoal, lime rubble, chopped straw, and peat are often added. Whatever is used, the compost in a dry state should be firmly rammed to ensure the passage of water through the old balls, and not an hour should be lost in getting the plants replanted in their new quarters. If the heat in the recently prepared bed is on the decline, 85° to 90° at the base of the pots will favour safe and rapid recovery from the check without the aid of water, but the syringe must be used for dewing the foliage and thoroughly moistening the walls on fine mornings, and again when the house is closed for the day. Light bright roofs may require a little shade for a few hours on fine sunny days, but this must not be carried to an extreme, neither must fire-heat be so strong as to necessitate the inlet of an abundance of fresh air. When the plants have taken to the soil, the first supply of tepid water may be given to the roots, and ordinary treatment, as a matter of course, will be resumed.

Suckers from late winter and early spring fruiterers should be potted up as they are detached and plunged in a brisk bottom-heat near the glass. Snug span-roofed pits heated with hot water and well filled with fermenting leaves answer best, but excellent plants in days gone by have been expeditiously made without the aid of fire-heat. The main factors in this mode of starting suckers are a steady bottom-heat ranging about 90°, good linings, and dry external covering through the night. A frame, in fact, that will produce good Cucumbers is an excellent nursery for summer suckers.

VINES.

Work in this, as in all other departments just now, is very pressing, but on no account must the most trifling details be neglected. Early houses in which the Grapes are ripe will require more air and less moisture, but the inlet of the first and the discontinuance of the second must be gradual. Indeed, early Vines, with three or four of the hottest months before them, must have a liberal supply of atmospheric moisture, and the Grapes will be none the worse for it, always provided there is a free circulation of air, and fire-heat is just sufficient to prevent condensation. A moist, growing condition of the internal borders is also essential to the keeping

of the Grapes, the production of laterals, and last, but not least, the prevention of the ravages of red spider, this year more plentiful than welcome. Outside borders, as a matter of course, still remain covered, and, be the material what it may, great caution must be brought to bear upon its disturbance. A few bright days in June may induce some to reduce, but this early move before we have true summer weather is dangerous practice, and then even sufficient to form a heavy mulch should be left until the time arrives for top-dressing in the autumn.

Mid-season houses.—Next to the daily routine of airing, syringing, and watering, the most important work will be stopping, tying, and the prevention of the spread of insects. Spider is the most troublesome—some say bug, but of the two give me the latter, as patience and methylated spirits will keep it out of the bunches, and the tar dressing in winter, without hurting the Vines, will annihilate it. If thinning and shouldering have not been brought to a close, advantage should be taken of cool mornings and evenings for taking out all stoneless berries and giving further relief where necessary. Grape-thinning is a tedious, but withal a pleasant occupation, requiring great care and skill, also a thorough acquaintance with the capabilities of the Vines, as some varieties, especially Hamburgs, vary so much in size of berry when ripe. Here we have a variety which produces large bunches and hammered berries often $4\frac{1}{2}$ inches round, and another whose bunches are large, but loose, with thin-skinned, luscious, oval berries, not nearly so large. The first requires as much thinning as a Gros Colmar; the second carries one-third more berries to the pound, and being loose-shouldered, these two require quite distinct treatment; otherwise the first will bind, and the second will fall literally to pieces when cut and placed upon the dish. When properly thinned, every bunch should retain its shape when cut and laid on its side, and yet all the berries should be fully developed. Ordinary Grapes do not require much shouldering; indeed, many good growers never shoulder at all, but gently raise the shoulders, to prevent the berries from binding. I am in favour of shouldering, and the majority of exhibitors who succeed in colouring large clusters adopt this method of increasing their size.

Late Muscats and Lady Downe's.—Having renovated my external border in the one and the internal border in the other house, in the latter, when the buds were swelling, the Vines have been allowed to break slowly, and although later than usual, the rods and foliage already prove that the roots are working in the new compost; which, by the way, fermented and stood for a long time at a temperature of 60°. Many growers are afraid of going vigorously into late borders when the buds are swelling; but this is their only course, and I can strongly recommend it. The cool system of starting throws away a little time in the spring, but early closing soon pulls it up, and renovated Vines always set and colour their berries well. Renovated Vines require heavy mulchings to draw the roots upwards, an abundance of atmospheric moisture, and, the better to stimulate fresh root-action, weak laterals should have full play, strong ones only being stopped until the trellis is covered with foliage. Beyond this no one attempts to go, but bearing in mind that the leaves are the lungs, an effort to get every square foot beneath the roof covered should stand first and foremost.

Thinning.—Lady Downe's and Alicantes cannot be thinned too early after they are set; in fact, the first operation is what I term cleaning—no bad practice for young fellows who require training into the handling of the scissors. Experienced hands, when stoneless berries lag behind, then follow, and this time over, completes the operation. Muscats, on the other hand, require a few days' grace to enable the perfectly fertilised berries to declare themselves. This stage reached, the thinning of a house of Muscats is a brief and, being the last, a very pleasant operation. Young beginners should bear in mind that early morning, when the body is cool and the muscles firm, is the best time to thin Grapes; further, they should never touch the berries

with the flesh or hair—a very common cause of rust, which can easily be avoided by the use of a small forked peg or hook; and on no account must the stalks or berries be injured by the scissors.

Pot Vines intended for next year's fruiting having been stopped at the proper height will now thicken amazingly. Good top-dressing and liberal supplies of diluted liquid may still be given to the roots, which, by the way, must not be allowed to run away into the plunging material. When a pot Vine takes its first hold of this, it puts on great force and looks extra promising, but the day of reckoning comes; therefore it is best to rest satisfied with firm short-jointed canes with plump buds which will ripen early. When the young rods begin to change to a bright cinnamon-brown, plenty of heat, but more air must be given, and the better to ensure prominent buds, all laterals, from the base to the pruning-point, must be closely pinched, those above being left for the present to act as safety valves. Cleanliness being important, the syringe must be freely plied to keep the foliage fresh and free from spider, as a fine show cannot be expected from buds whose main feeders are injured or destroyed.

FIGS.

By this time many early houses will have been cleared of the first crop of fruit, and although the second may be well advanced, there will be ample time for carrying out the extermination of insect pests which dry heat may have established. These, in sharply forced Fig houses, unfortunately are numerous, but there are few which can stand against incessant syringing, either with pure water or safe and well-tried insecticides. Red spider, mealy bug, and brown scale form a formidable trio, which can only be checked during the time the fruit is ripening; not so when the crop is off, as pure water, applied with some force, will break up the web of the first; repeated syringing with paraffin and water, a wineglassful of the first to three gallons of water, will melt bug; and water uncomfortably warm to the hand will check, if it does not completely destroy the scale. A single application may not suffice, but constant attention for two or three weeks will produce the desired effect. In order to have the second crop fruit fine, fresh mulching and copious watering with weak stimulants must not be neglected, neither must the thinning of the wood and fruit be overlooked. Ventilation, now the weather is getting warmer, must be on a more liberal scale, for without fresh air and plenty of light neither colour nor flavour can be secured, and, it is needless to say, a pale vapid Fig is useless and uneatable. Heat, as a matter of course, is imperative, as good fruit cannot be obtained without it; therefore, until the nights become much warmer, the pipes must be regularly warmed to ensure a minimum temperature of 65° to 70° and a maximum of 80°.

Succession houses.—If started at the right time, ripe fruit from these should be ready for taking up the supply. When the flowering stage is complete and the fruit changes from a dense green to a paler colour, the syringe must be confined to the stems and walls, as direct syringing is one of the common causes of cracking. The floor of the house, too, may be liberally damped on fine days, when danger of condensation and spotting will be reduced to a minimum by a free circulation of air. If the fruit is wanted for home use it may hang until quite ripe, and then, provided the house has not been kept too close and moist, sound Figs will keep for a few days in a dry airy Grape room. Connoisseurs do not object to a fine fruit that has cracked or is slightly on the change, but for market purposes it must be sound and perfect, and, as a matter of course, not over-ripe.

Late houses from which not only one, but a successional, crop is expected best answer this purpose when the trees are trained on the extension principle and stopping or pinching is omitted. As these are supposed to ripen their fruit and wood without the aid of much, if any, fire heat, the young shoots should be laid in thinly, and moderate growers, like Brown Turkey, White Marsilles, and Negro Largo, which produce as many fruit as

leaves, give the best result. The better to secure this fertility the roots should be checked annually, the root run limited, and the compost not over rich. Plenty of water through good mulching when the fruit is swelling, of course, is imperative, but the first may be considerably reduced and the second partially removed, also half-swelled Figs rubbed off when the time arrives for ripening up the wood.

Pot trees intended for next year's early forcing should now be shifted for the last time and plunged in a light pit with just sufficient head room, and not too close together. When they have taken to the compost, consisting of friable, turfy loam, old lime rubble, and crushed bones, weak liquid may be freely used to favour the rapid formation of roots, a pot-bound condition being one of the essentials to thoroughly ripened trees fit for forcing. The syringe here, as in fruiting houses, will play a very important part, and early closing, with strong sun heat and vapour, will hasten recovery from the slight check which generally follows repotting. If pinching becomes necessary to the formation or shape of the trees, it should be discontinued after the end of this month, otherwise newly-formed points will not have time to ripen. W. C.

Asphalte walks.—It is a mistake to attempt to make tar-paved walks with ashes or any other substance which will not withstand wear. Further, unless the materials used with the tar are previously burnt like ballast, or roasted and mixed whilst hot, the work will be unsatisfactory. The tar should also be in a boiling state; the mixture of pitch I consider of no value. First choose stone of a flinty nature, make a fire of wood and cover with coke, breeze, or small coal; put on a layer of stone; throw more of the above fuel over the stone, then another layer of stone, and repeat the operation until sufficient for the purpose has been burnt; it matters not if some of the stones are large, the heat will act on them, as water does upon lime. Whilst as hot as it is possible to work, sift into two sizes—the rough for foundation of the walk, the finer for the surface. Mix thoroughly with boiling coal tar upon a platform of planks and put in heaps for use, care being taken that the material for the top layer consists of pure stone and tar, all dirt and dust being sifted out before using. Should it be any considerable time before it is used, it may be necessary to sprinkle some boiling tar over the material to make it work. I may mention that any handy labourer who has burnt ballast would be able to burn the stone. Having the material ready as above, the next consideration is the foundation of the walks. This should be perfectly solid and in no way liable to sink. The rough material should then be laid on about 2 inches in thickness and firmly rolled; then lay on the finer coating of the paving to a depth of about 1 inch, and again roll firmly. Too much stress cannot be laid on the importance of rolling, as the heavier the roller the better. One of stone is the best for the purpose. Edgings of wood, tiles, brick, or other suitable material are necessary to prevent the sides crumbling away. The surface should then be sprinkled over with coarse grit, crushed shells, or spar, and again well rolled. As regards maintenance, the only work necessary is to brush hot tar over the surface periodically and throw over, as in the first instance, crushed shells or fine sharp sand. The above method will give a sound walk alike in all weathers, cheap to maintain, upon which weeds will not grow, and from which no perceptible odour of tar will emanate if properly done. The mixing process is that which requires most experience, as it is always most satisfactory when performed at the right heat.—E. D.

Grubs in soil.—Would you kindly tell us the name and nature of the grubs sent herewith, and whether they are in any way injurious to plants? We find them in clusters round the roots of plants in the open ground.—COLLINS BROS. AND GABRIEL.

* * * In reply to Messrs. Collins Bros., the grubs are the chrysalides of a fly; in their present inanimate condition they are quite harmless. From their position near the roots of the plants I imagine the grubs had fed on the roots until they were full grown, when they turned into chrysalides. Turn up

the soil when practicable and give the birds a chance of getting at the grubs, or give a good dressing of lime or soot to the surface, which may prevent the flies when they emerge from the chrysalides leaving the soil.—G. S. S.

FERNS.

W. H. GOWER.

ONYCHIIUM AURATUM.

THIS is a member of a small genus nearly allied to *Pteris*. It is a native of Assam and Nepal, where it is found on the mountains up to between 4000 and 5000 feet elevation. It also

Onychium auratum. Engraved for THE GARDEN from Nature.

occurs in Burmah, New Guinea, and several of the Malay Islands. The illustration here given was taken from a side pinnule of a frond sent from Upper Assam, a glance at which will convey a better idea of its beauty than volumes of words. The fronds grow from 1 foot to 2 feet in height, supported upon a pale yellowish brown stem; the texture is coriaceous, and the colour rich deep green. When fertile, as our engraving shows it, the broad membranous involucre and sori are bright golden yellow, which produces a fine contrast with the vivid green of

the infertile fronds. In this latter state the segments are more finely divided than when fertile. It requires stove temperature, and should be grown in soil composed of about three parts turfy loam and one part each of peat and sand. The spores do not appear to grow readily; therefore increase must be effected by division, which is best done just before new growth commences early in spring.

OUR NATIVE FERNS.

THE HARD FERN AND ITS MOST DISTINCT VARIETIES. Although a thoroughly British plant, the Hard Fern (*Lomaria Spicant*) is one of the most cosmopolitan species known, as, besides its being found in a wild state in almost all parts of Western Europe, it is equally common in Denmark, Sweden, and Norway, also in North-west America. It is even found in the Canary Islands and at the Cape of Good Hope. In England it has been found in St. Faith's, Newton Woods, near Norwich; at Brousgrove Lickey, in Worcestershire; in the Vale of Dodecombe, near Painswick; at Hainsford, in Norfolk; in Anglesea, in various parts of Hertfordshire, and of the northern counties. It is also spread all over Ireland, but principally in the counties of Wicklow and Clare. It is found in Cumberland and in Forfarshire at an elevation of 700 feet to 800 feet above sea level; but in Aberdeenshire it occurs on the Cairngorm Mountains at much higher altitudes, varying probably from 1000 feet to 1200 feet. Gerard, in his "Herbal," says: "It groweth in most parts of England, but especially on a heath by London, called Hampstead Heath, where it groweth in great abundance." However abundant it may have been in that locality in Gerard's time, it is now pretty well extinct there.

The Hard Fern is one of the commonest of our evergreen species, and its striking habit, as well as the rich deep green colour of its barren fronds and its evergreen nature, render it one of the most useful plants for the decoration of the outdoor rockery, where, in a moist shady nook, it forms a very beautiful and most conspicuous object. Its habit is very compact, forming a dense mass of fronds which are of two entirely distinct characters. The barren ones, which are very numerous and vary in length from 8 inches to 12 inches, are evergreen and become prostrate. The fertile fronds, on the contrary, are always erect, and vary from 12 inches to 20 inches in height; they are also less numerous and of a more scanty appearance, as their leaflets are much narrower through their edges being recurved; they are besides more pointed and more distant from each other than those of the barren fronds. The Hard Fern is one of the least fastidious of all our British species, for although it prefers moist situations with a northern aspect, it also succeeds in a stiff, clayey soil and when exposed to the more or less direct action of the sun's rays. If it has its preferences, the Hard Fern, according to the authority of some practical men of great importance, has also one very decided antipathy—it dislikes lime in any form. Messrs. A. Stansfield and Son, of Todmorden, Lancashire, who for many years have made a speciality of the culture of hardy Ferns, and whose name in connection with that interesting class of plants is generally associated with those of eminent men like Moore, Woollaston, R. Sim, Ivory, &c., referring in their catalogue to the antipathy of this Fern towards limestone, give it as their opinion that "lime appears to be as injurious to the *Lomaria Spicant* among Ferns as it is to the common *Ling* among flowering plants. Lime in all its forms, therefore, should be avoided; even water containing lime should not be used." A fact of primary importance, and one which may be taken as a safe guide in its cultivation, is that in its wild state it is found in perhaps a greater variety of soils and situations than any other of our native Ferns.

Although the genus comprises only one solitary species, this latter has produced naturally, and also through cultivation, numerous interesting varieties, the most distinct and most attractive of which will deserve special attention on the part of all Fern growers, the more so that, in hardness or in decorative qualities, they are equal to the species from which they are raised.

Several crested forms of the Hard Fern are in commerce; among these we note *Lomaria Spicant cristatum*, whose fronds of normal shape seldom exceed 9 inches in height, and differ from those of the species in having their apices furcate or crested. This form has been gathered in a wild state in several places, notably in the neighbourhood of Tunbridge Wells. In *L. s. Aitkinianum* we have a remarkable crested form found some fifteen years ago in the west of Ireland; it is essentially distinct from all other crested varieties on account of its having its fertile as well as its barren fronds terminating in large crested and ramose heads; but that extraordinary development does not show itself until the plant has attained full dimensions. The best, however, of the crested forms is *L. s. ramosum*, which is a variety with short, prostrate, barren fronds, each of which are divided at their extremity into two branches, each again repeatedly branched. The ultimate branchlets are very crispy, and form a nearly circular crest, fully 3 inches across. The fertile fronds, which have their divisions contracted like those of the species, are similarly taller, erect, and produced from the centre of the crown; they are equally furnished at their extremity with a crest, which, however, is of smaller dimensions than those found on the barren fronds. The splendid variety called *L. s. multifurcatum*, without having its fronds properly crested, is exceedingly ornamental; for the barren fronds, which are nearly prostrate and comparatively very large, measuring, in some cases, 2 inches in width, all end in a termination of five or six forked-branched points of a particularly flat nature, and measuring 3 inches or 4 inches across. It is an extremely rare Cornish variety, whose fertile fronds, nearly erect, possess an equally many-forked termination. Of the other forms, that cultivated under the name of *L. s. projectum* is probably the most extraordinary sport known. Its fronds, of dimensions similar to those of the species, possess a very curious appearance, as they are narrow, and in some parts almost entirely deprived of lateral lobes on each side of the stalks. In some fronds the lobes are extremely short, but at intervals come out to the usual size. It is very curious and distinct. Equally pretty are the varieties *concinnum*, *anomulum*, *heterophyllum*, and *variabile*; while an entirely different appearance is possessed by *L. s. caudatum*, with its short and narrow barren fronds tapering towards the point into an undivided tail-like end. The same may also be said of *L. s. imbricatum* and its sub-varieties *crispum*, *erectum*, in which the fronds, about 8 inches long, are nearly ovate, often symmetrically arranged, with their lobes so markedly overlapping as to make the frond appear almost double. In most of these imbricate forms it is remarkable that the fertile fronds are very little longer than the barren ones, and that in the sub-variety *erectum* their lobes are turned back so as to form almost a cylinder.

The compost in which the Hard Fern and its varieties grow most luxuriantly is one made of loam, peat, leaf-mould and sand in equal parts. In planting, it will be found most beneficial to the plants to intermix, if possible, some small fragments of broken sandstone through the compost, which will thus be rendered more permeable, although retaining at the same time its permanently moist nature. It is in great request for the hard fernery, but, like many other British Ferns, it may with great advantage be equally used for the decoration of the greenhouse and conservatory, as some very handsome specimens of it in 5-inch pots, annually produced by some of our market growers, abundantly testify. This, however, is not by any means a new notion, as more than twenty-five years ago a writer says:—

Having grown it to a great extent, I can say, confidently, that it will grow, and that, too, most luxuriantly, in a

greenhouse. I have had plants of it in 8½-inch pots throw out eight-and-thirty fronds, fourteen of which were fertile; and it was that, and a fine plant of *Scolopendrium undulatum*, that attracted the notice of most visitors, for they were really noble plants.

The most common, as also the most reliable, method of propagation employed for the increase of the varieties of the Hard Fern is by division of the crowns, as very little dependence can be placed on their reproducing identically the varieties in any other way; but the species, although sometimes also propagated by division, is much more readily reproduced by means of seed, the spores being ripe about the beginning of September.

S. G.

ROSE GARDEN.

T. W. GIRDLESTONE.

ROSE NOTES.

WHIT SUNDAY come and gone, and the only Roses in bloom the extremes of prickly and prickless—the alpine Rose without a thorn, and the thorniest of Roses, *R. spinosissima*. No *Maréchal Niel* or other Teas on the walls out of doors in May this year, nor any great prospect of their presence until after the middle of June. In fact, the plants on walls do not seem a bit forwarder than the plants in the open, though if the sun were to shine a little, they would probably not be later in bloom than last year. Some of the single Roses are doing their best to try and give colour to the seemingly incredible assertion of the almanac that it is summer time, for in addition to *R. alpina* and *R. spinosissima* above mentioned, *R. kantschatica* and some of the garden varieties of *R. rugosa*, such as *Comte d'Éprémesnil*, are showing their petals, and a gleam of sunshine would bring out *R. myriacantha* and all the *spinosissima* progeny of the tribe of double Scotch Roses. The Austrian Briers, too, promise wonderful bloom at an early date, and *R. polyantha* seems masked with a more solid sheet of buds than ever. All these Roses and the plants of *R. macrantha* about whose situation "*Hortus*" inquires are growing here, *Summingdale*, Berks, in front of an 8-foot split Larch fence facing south-east, in a part of the garden sheltered from high winds, but which from the proximity of buildings and trees, does not get either the early morning or the late afternoon sun.

Unfortunately, several instances of Orange fungus have already been observed upon some of the Scotch Briers, as well as upon one or two sucker-like shoots from the base of some dwarf Hybrid Perpetuals. It is generally on those shoots that come from below or very near the ground that this pest is first seen, and as the resting spores of the Orange fungus lie on the ground through winter, ready to attack any Rose growth with which they may be brought into contact in the spring, perhaps the exclusive cultivation of standards on a piece of ground where the fungus was troublesome might secure its extermination. It has been suggested that as Hollyhock disease was probably brought into gardens by the common Mallow, so the increased use of the Brier (which is liable even in the wild state to the attacks of Orange fungus) as a dwarf stock may partly account for the recent prevalence of the disease in gardens. This, however, is hardly probable, for, in the first place, hardly any other stock than Brier was formerly used for garden Roses, and in the second place, dwarf plants on *Manetti* have of late years been overwhelmed with red rust, while dwarf plants on Brier close by have almost entirely escaped. A parallel is found in the case of mildew, which hardly ever attacks the *Manetti* itself, while Briers, especially in the

seedling form, are frequently smothered with it; and yet time after time plants worked on *Manetti* have been seen white with mildew when plants on Brier in the same garden have been green as Leeks. Mildew, however, is not so unmanageable a plague as Orange fungus, for the avoidance of a visitation of which no amount of pains devoted to the hunting for and destruction of every bit as it appears can be considered as misapplied.

Orange fungus.—This pest has made its appearance to-day (Whit Monday) on a plant of *Madame Montet* and on a plant of *Duke of Edinburgh* in quite another part of the garden. The two or three affected leaves have been burned, and a careful search has failed to discover any further symptoms of the disease. The plants above mentioned are on beds quite 100 yards apart, and no reason is apparent why they should be touched and other plants escape. It is to be feared, however, that there will be no difficulty in finding other cases in a few days. Last season the first appearance of the fungus was noted on the 7th June.—NORTH HERTS.

Rose Lady Mary Fitzwilliam.—This grand Rose well merits all the praise that Mr. Girdlestone bestows upon it (p. 457), and it has this additional recommendation that it forces well, and with little trouble makes a first-class pot Rose. I first saw it at the National Rose Society's Show at South Kensington in 1883, and I forthwith obtained plants from Mr. Bennett, the raiser. These were turned into the open border, but they made little growth, and a few buds were secured with difficulty. Two years later the same plants were repotted and grew away, and this spring they were pruned early in February and placed in heat. Notwithstanding the cold, sunless spring, they grew well, making new shoots 18 inches in length, and bloomed magnificently—form, size, and substance being all that could be desired. In working stocks, too, the buds of this Rose seem to take better than those of almost any other variety; but it is well to select them as far as possible from the base of shoots, the habit being so floriferous that, if taken from near the flower-bud, they often grow for an inch or less and then attempt to flower on their own account. Having said so much for this Rose, it must be admitted that in the open it strongly objects to rain, or even dew, yet seems to find considerable difficulty in keeping its outer petals clean, and shows here a decided preference for the standard over the seedling Brier as a stock.—NORTH HERTS.

SHORT NOTES.—ROSES.

Rosa berberifolia.—Some time ago I received some further information about the habits of this Rose. It is found on rocky slopes, sometimes in patches and sometimes in single specimens growing in small fissures, where the roots are cool and somewhat moist, and the top exposed to the aridity of an Afghan summer, or to the sharp cold of a Central Asiatic winter. If we could imitate these conditions approximately, there would be no difficulty in the cultivation of it in plant.—MAX LEICHTLIN.

Maréchal Niel Rose in the open air.—Now and then a good specimen of *Maréchal Niel* is seen in the open air, but as a rule it fails to grow and bloom satisfactorily out of doors. The growths in the open do not generally develop freely, and the blooms rarely appear in any quantity or in first rate condition, and although finely coloured blooms may sometimes be gathered from a plant on a sunny wall, disappointment will be the rule. Let those who have a greenhouse plant it there.—J. MITCHELL.

Tussocky Grass parks.—The complaint of Mr. F. Manson the week before last is a common one. Grass lands laid down permanently around mansions do get tussocky unless cut, burned, or limed and chain-harrowed severely. The rough patches get as thick as a mat, and cattle will not eat them down. In some parks the whole bottom gets too thick, and when in that state it is a long time before the Grass gets green in spring—not until the young Grass has grown through, and the crop is never so good. In the old deer parks here it would require a heavy steam harrow to tear up the matted bottom. Liming and burning are both resorted to, but the fire just singes the tops of

the Grass, and liming is an expensive matter over many hundreds of acres. I have seen a good dose of gas-lime, put on early, burn every particle of herbage off to the roots, and a fine, even short pasture result afterwards. A small park like that of Mr. F. Manson's might soon be cut bare enough with the scythe. A man should go over the rough patches and shave them off close to the soil. Afterwards the tops should be burned along with any other combustible rubbish, and the ashes scattered over the ground. If the patches consist of coarse Twitch and other uneatable Grasses, the patches should be pared and burned, and it would pay to do so, because a well-grassed park grazes the most cattle or sheep. Plenty of cattle should be turned in at this season; they will tread and eat it down wonderfully, and can afterwards be reduced in number. S. W.

KITCHEN GARDEN.

W. WILDSMITH.

ASPARAGUS NOTES.

It is a singular thing that, although Asparagus grows wild not far from here, its culture is still looked on as a mystery only to be known to the few, while to the majority it is still a forbidden luxury owing to its prohibitive price, and the foolish nostrums that are said to be necessary for its culture. Anyone who can grow good Potatoes or Cabbages can grow Asparagus, and why it has been so long banished from small gardens is a problem few could solve. In the neighbourhood of Southampton I have seen it growing wild close to the water's edge, where the salt spray dashes over it in times of storm and flood. Where the soil is sandy and well drained it appears to thrive amazingly and to be long lived. A plant that will spring up and grow freely in a gravel walk can hardly be said to need much coddling. The one thing that I find Asparagus does not like is a cold stiff soil, for, although it will grow in any soils, the roots perish in winter in those that are cold and undrained; if, however, it is porous, Asparagus will thrive, and the poorest soils may be made into prolific Asparagus beds by the addition of manure, sea-weed, or town refuse. It is one of the crops that ought to be largely grown on some of the south coast farms that are going begging for tenants, who cannot make cereals pay, and do not appear to know of any other crop. It must be a very poor crop of this vegetable that will not return more profit to the grower than the best crop of corn that can be grown. Certainly bundles of Asparagus, although they may be kept longer than many vegetables with the stalks in water, are never so good as when fresh cut, and I feel sure that anyone growing it very largely near the coast, where the soil is especially favourable, would find it a good venture. The first thing to do in growing Asparagus for profit is to provide the plants at the cheapest rate, and for this purpose there is little difficulty in the matter, as no plant is more readily increased from seed.

SOWING THE SEED should be done in March or April at the latest, and enough plants for an acre may be raised on a small plot. Conover's Colossal, Battersea, or Grayson's Giant are good selections, and if sown thinly in drills 1 foot apart, and allowed to stand one year, nice plants fit for planting in April or May, according to locality, will be found the following season. I like to plant just as the young growth is pushing through the soil, and if one has the plants close at hand, they can be removed from the seed-beds to permanent quarters without injury to roots or tops after growth has started. If procured from a distance, it is best to get them when quite dormant, for the reason that the roots are much less liable to injury from becoming dry, and the crowns are all closely folded up, and therefore safe. In preparing the soil for new beds, it is advisable to trench or loosen the soil two spits deep, but if of poor quality, too much of the lower spit should not be brought to the surface, as in this locality a great deal of the soil is too shallow to admit of trenching in the manner in which it is done in deep alluvial soils, yet it grows

Asparagus to perfection after it has been well loosened and the top spit well enriched. Manure should be mixed with the top spit, but it is a mistake to bury it deeply in gravelly soils, as the nutriment gets washed away into the sub-soil before it can be taken up by the roots, and a little spread on the surface after planting will do more good. If this work is done in winter and the surface left rough for the frost to act on it, there will be little needed at planting time beyond marking out the beds and drawing the drills. Beds about 1½ feet wide are the most convenient, and three rows of plants are sufficient. Stretch the line down the centre and draw a deep drill, and in this spread out the roots of the young plants, then give them a coating of sand (sea-sand answers well), and return the soil; draw the two outer lines at equal distances from the centre and edge of the bed, and treat like the first row, and then add a little soil from the alley, and the work is complete. The attention during the first year after planting will be simply to keep the surface free from weeds, and in winter, as soon as the tops die down, cut them off, and give a good coat of manure on the surface, leaving it rough throughout the winter; and in spring, before growth commences, rake it down fine, and cover with soil from the alleys. Never dig between the beds low enough to disturb the roots, as the best feeding ground is in the alleys, and if growers value their Asparagus, they will not crop the alleys after the beds begin to bear.

During the second year after planting the growths made by the tops should reach 5 feet high, and, to prevent injury from wind, some good stout Pea sticks should be inserted along the sides of the beds, as on the perfect maturation of the top growth will depend the strength of the growths the next year. Beyond keeping free from weeds, little other work is required until winter, when the tops must be cleared off and the beds dressed with manure as before. A good sprinkling of salt in spring not only assists growth, but helps to keep weeds in check. The third season after planting very fine shoots should be produced, but it is not advisable to cut young beds too hard or too late in the season, as with careful treatment Asparagus beds should remain prolific for at least twenty years.

If one has not got space for beds, very fine produce may be grown by putting in a single crown in any vacant space, such as between bush fruits or similar spots. I have a very fine root that never fails to send up a quantity of the finest shoots from a self-sown plant that sprang up close to the stem of an Apple tree, where we let it remain, and without any special preparation it is very prolific. In fact, a dozen good clumps or single crowns would yield a nice dish a good many times in the season, and the only attention these single clumps require is to support the growths with good stout stakes when the season for cutting is over, and when cut off in winter a dressing of good rich manure or compost should be given. Anyone giving this system a trial will be astonished at the results.

Hints.

J. G.

KITCHEN GARDEN NOTES.

PLANTING.—The prevalence of dull, showery weather has so favoured the planting out of sundry crops, that we have been induced to do more of that kind of work than otherwise we should have done, at least, in such quick succession. Celery planting is all but completed; another small batch of Autumn Giant Cauliflower has been planted, also a few Savoys and Autumn Protecting Broccoli, and having an extra good lot of Lettuce plants—the thinnings from a recent sowing on a west border—we have planted out the best on a north border, on which aspect they will probably do as well as if they were sown where they were to mature, the latter way being our usual practice during the summer time.

THINNING OUT SEEDLINGS.—Here, again, the weather has helped us greatly, and we are now nearing the end of thinning out Parsnips, main crops of Carrots, Beet, Onions, Leeks, Salsify, Scorzonera, and Dandelion. As soon as the thin-

ning out is finished and the ground a little drier, the hoe will be run through them all. From some of the best kinds of Potatoes the weakest part of haulm has been pulled up, as by these means more even sized tubers are obtained, but the practice has no other merit, and except for certain purposes, such as for exhibition or for trial as to the merits of a variety, it is not worth while to put the plan in practice. Cauliflowers wintered in handlights have not done well; the winter has been too long and too severe; many are very poor, and none will be first-class nor even equal to the Late Queen Broccoli that we have still in good condition.

SEED SOWN.—Another sowing has been made of Lettuce and Endive in drills a foot apart, Turnip-rooted Radish between the rows of Peas, Canadian Wonder French Beans on ground recently cleared of Broccoli, and which we deeply dug and manured. A long row each of Ne Plus Ultra, British Queen, and Latest of All Peas in trenches the same as for Celery has been sown. Before another sowing can be made, the ground now occupied with Purple and White Sprouting Broccoli must be cleared, heavily manured, and deeply dug or else trenched. I am a strong believer in what Mr. Gilbert calls "everlasting digging," and if he had such a hungry, sandy soil to deal with he would soon change his opinion, for if he did not trench at least every alternate year supplies would run short.

STAKING AND TYING.—Tomatoes do almost equally well with us on warm borders as they do on the walls, and to those thus planted stout Alder rods 4 feet long have been placed and the plants tied thereto. The plants are only allowed to have one principal stem, suckers from the bottom being persistently pinched back, but the laterals from the main stem are allowed to extend considerably, and when they get so long that support is needed to keep the fruit from breaking off the shoots, they are looped up to the main stem and tied to the stake. The plants are all a yard apart, and the whole of the ground is thickly mulched with strawy litter; hence they are cleanly to work amongst, and artificial watering is only required in seasons of exceptional drought. Staked runner Beans; a double line of sticks the same as for Peas is our plan of doing this; the tops are pinched out, which conduces to lateral growth, and of course of shorter height, and, what is still better, a longer succession of Beans. The main sowing recently made consists of two rows 6 feet apart; these we shall stake in the form of an arch by bending the sticks from one row to the other and roughly tie the tops together at a height of 6 feet, which will allow of head room for gathering the produce. We endeavour to stake all Peas as soon as they are well above ground, then no injury is caused by disturbance of roots, and, what is of some account, the work is off hand, and we are thus saved the unpleasant feelings that are begotten of procrastination. New growths on young plantations of Asparagus that are too long and slender to support themselves will soon require to be staked; this we do with small Hazel sticks and tie with netting. Onions for seeding we do in the same way, and for the strongest growing dwarf French Beans we use the twigs obtained by cutting up worn-out Birch brooms.

GENERAL WORK.—Hoing all crops that cannot be mulched, and where the latter is done hand-weeding is the only means to keep these down. Train out and soil up Ridge Cucumbers; plant others, also Vegetable Marrows and Capsicums; thin out, and in some instances prick out, Broccoli plants; make other sowings of Beet and Parsley; clip Box edgings, surface the walks with fresh gravel, and well roll the same after a heavy rain.

W. W.

SHORT NOTE.—KITCHEN.

Pea Laxton's Unique.—This is a very dwarf early variety, and is well adapted for sowing at the foot of a Peach wall, and also in frames for an early supply. It is a first early and very dwarf, a free bearer, and produces capital pods for its size. I saw it at Wyconhoe Abbey Gardens the other day at the foot of a Peach wall, and already in bloom, and not more than a foot above the ground. Gardeners should note it as a very desirable variety for early work.—R. D.

TREES AND SHRUBS.

W. GOLDRING.

THE HYBRID SERVICE TREE.

(PYRUS PINNATIFIDA.)

AFTER the Pears, Apples, and Cherries are out of bloom and before the Thorus flower, the hybrid Service Tree is conspicuous in plantations and gardens on account of the profusion of its white bloom and peculiar form of growth, which is distinct from all the innumerable members of the Rose family. Though a native tree, it is not commonly seen except in gardens and parks where tree planting has received due consideration, yet it is a most valuable tree, possessing an individuality which it never loses, for even in winter it may be singled out from all others by its growth. The growth is very dense, always forming an elongated, globular head, and is never very tall, the largest trees being only from 20 feet to 30 feet in height. It is supposed to be a hybrid between the Mountain Ash and the White Beam tree (*Pyrus Aria*), or at least a variety of the latter named *intermedia*. The deeply lobed leaves, the dense clusters of flowers, and scarlet fruits are all characters that render the tree intermediate between the Mountain Ash and the White

The pinnatifid white beam tree (*Pyrus pinnatifida*).

Beam, but if it is really a cross between these trees it must be a wild hybrid, as it is indigenous to various other parts of Europe besides Britain. But its origin and name are of secondary consideration, our only motive for writing about it being to draw attention to what seems to us a neglected tree, one that properly employed would add interest to ornamental plantations throughout the year. It is very hardy, thrives in any soil; prefers shade, but does not refuse to flourish on an exposed hillside.

The American Wych Alder (*Fothergilla albifolia*).—This North American plant is very rarely found in British gardens, yet it is when in flower very pretty, and also quite distinct from any other shrub. It is deciduous in character and reaches a height of 3 feet to 4 feet, while the leaves, which are rather late in expanding, are preceded by the flowers. The principal feature about the bloom is the cluster of stamens, and as several flowers are borne in a bunch quite a roundish mass of them is formed, and being white they stand out very conspicuously from the dark-tinted bark of the leafless branches. The blooms are also agreeably scented. This Alder does not succeed in a hot, dry spot, but is seen at its best under conditions that are favourable to Azaleas and such like

plants. To the lover of uncommon and, at the same time, pretty shrubs this can be recommended. According to London, it was introduced into this country in 1765. There are two or three varieties, but none of them are superior to the type for ornamental purposes.—T.

Double-blossomed Furze.—In a selection of flowering shrubs for dry, sandy spots this must not be passed over, for it is now one of the most showy of all in bloom, and, as an additional merit, retains its beauty a considerable time. When growing on some distant knoll it stands forth in the sunshine like huge masses of gold, and its drought-resisting qualities enable it to be planted in such spots. Cuttings of it put in a sheltered border in early autumn will strike root, and if put in soon after midsummer and protected by a frame they will then strike before the winter. The double-flowered Furze, like its common relative, will grow well in all kinds of soil, and flower profusely provided it is in a sunny spot.—H. P.

The large-leaved Storax (*Styrax grandifolia*).—I send you a specimen of *Styrax grandifolia*, one of our most beautiful native shrubs. It is of free growth and a profuse flowerer. There are bushes in my nursery, from 8 feet to 10 feet in height, literally covered with flowers. This shrub would prove perfectly hardy in England if provided with a dry, warm position to mature its growth, and very few shrubs can approach it in beauty when in flower. A native of the mountain range through the Carolinas and Georgia, from whence comes

some of the finest shrubs and trees in cultivation. It is a common practice in England to grow this class of plants in peat, which is by no means necessary, as all will grow freely in a well-drained loam. — JOHN SAUL, Washington, D.C.

Cratægus pinnatifolia.—It is rather surprising that this Thorn is not more common, as it is a distinct and beautiful species, but one whose most prominent feature is not its blossoms, but, in early spring, the beautiful tender green of the expanding foliage. The matured leaves, too, are very handsome, for they are as much as 6 inches long and deeply pinnate. Besides this, the leaf-stalks are very long, and so weak that the foliage is partially pendulous. Its beauty is much enhanced by the fact that it is in full leaf while all of its allies (except the Glastonbury Thorn) are still in their winter garb. Though the young foliage appears so delicate, it is proof against spring frosts. This Thorn is a native of Eastern Asia, and is a great acquisition among hardy trees and shrubs.—H. P.

Early Rhododendrons.—There are no doubt good reasons why early-flowering Rhododendrons are not more commonly planted, the chief being that in some years they bloom so early, that their flowers as soon as opened are damaged by frost. But this evil does not occur every season, and certainly it has not this year, for the early sorts are now the glory of many a garden, in many instances

affording the only brilliant colours, for Lilacs, Laburnums, and Thorus are long after their usual date of blooming. In ordinary seasons, Rhododendrons, like the old *Russellianum*, *Hogarthii*, and others, do not show themselves, because they are either kept back by the weather or are put in the shade by the profusion of the later varieties. The majority of the early sorts have presumably descended from the high-coloured and early-flowering *R. arboreum*, and this accounts for their comparatively tender nature. But even if we can enjoy the beauty of a brilliant Rhododendron bush in early May only once in three seasons, is it not worth while to plant a few about a garden? A glint of bright colour in May in a garden is more enjoyable to many than all the splendour of lavish profusion of flowers in midsummer.—G.

THE WAYFARING TREE.

(VIBURNUM LANTANA.)

IF this tree was less common it would probably be better appreciated. It certainly cannot vie with its near relative, the Guelder Rose, but as it comes earlier into flower and will grow well in the most unfavourable situations, it deserves attention. The flower itself is almost white, but the yellow anthers, being prominent, give to the whole a creamy colour. It is not only for the sake of the flower, however, that this *Viburnum* deserves notice, as for seven or eight months of the year it is a conspicuous object. It is amongst the first in the spring to show its mealy buds, and the leaf-development commences whilst the majority of trees are bare. Now it is in flower. Its berries, which will shortly appear, will undergo changes from red and yellow to black. As the leaves commence to decay they assume a crimson hue, which, if less delicate than that of its sister species, always arrests attention. The wood of the Wayfaring Tree is amongst the toughest of any of our common trees and shrubs. Abroad the young growths are used for tying fagots and similar purposes for which the Hazel or Willow is generally employed in England. Less common subjects are naturally enough selected for isolated lawn planting, otherwise this *Viburnum* is very effective when kept to a single stem. There is a good example of this near here, and the tree is now a perfect mass of bloom. Within a short distance of my house the road is lined on both sides with this tree, interspersed with Hawthorn. Just at this season it forms a splendid vista, even with the disadvantage of being intermixed with other things. Although it grows so freely on very poor soils, I do not regard it as being altogether fitted for forming strong fences—*i.e.*, by itself. To form a compact fence it is necessary to have a plant which will bear and look well under rather severe and frequent pruning. For this the Wayfaring Tree is not well suited, as it is always seen at its best when allowed to grow at will. Within an iron fence by the roadside there is nothing which can excel it. I have enumerated above some of its qualities, and to this must be added its apparent disregard of dust. In seasons when the roadside vegetation is almost choked by dust, this tree seems to continue its growth unaffected. As a covert plant it has certain recommendations; but, on the whole, there is no better place for the Wayfaring Tree than that where its name implies—*viz.*, by the wayside. Along the margins of plantations which skirt the highway, behind dead, or under certain conditions live fences, it seems peculiarly at home. Owing to the abundance of its fruit and the ease with which it may be propagated, it practically costs nothing. In some ornamental groups which have been recently formed in a park near here I see it has been somewhat freely used, in spite of its being so common in the hedges. D. J. Y.

The Golden Heather.—The common Ling or Heather is very prolific in varieties, ranging from the loose straggling kinds to some of quite a dense Moss-like growth. The golden variety forms a low, spreading mass, and it is now very prettily suffused with a bright golden tint, which, as the summer advances, becomes tinged with bronze. It is rendered additionally effective when in proximity to

some of the darker-leaved kinds, and supplies a shade of colour that is not found in the blooms of any of them. From the many ornamental qualities possessed by these hardy Heaths a collection of them is always of interest, and is rarely without flowers; for some forms of the Heather will bloom till autumn is far advanced, and early in the new year the pretty little *Erica carnea* or herbacea commences to unfold its blossoms.—T.

The Golden Barberry (*Berberis stenophylla*).—Among spring-flowering shrubs this Barberry stands in the front rank, for it is a most beautiful object when the long, gracefully-disposed shoots are wreathed with golden blossoms. It is preferable to *B. Darwini*, whose rather stiff habit is not nearly so pleasing as that of the more graceful *B. stenophylla*. This last is generally recognised as a hybrid between Darwin's Barberry and the Fruegian Barberry (*B. empetrifolia*), but though frequently quoted as such, I am not aware of its origin, and should be greatly obliged if any of your correspondents could enlighten me upon that point. Such information would, I am sure, be valued by many. We employ *B. stenophylla* for flowering under glass here in early spring, and if not forced too quickly it blooms in a very satisfactory manner.—H. P.

The Scarlet-fruited Thorn This is among the earliest to bloom of all the Thorns, and its ornamental qualities rank high, for it forms a handsome medium-growing tree, the foliage of which is of a lively green tint, and in autumn it dies off tinged with yellow and red. Just now its wealth of white blossoms renders it conspicuous, and they are succeeded by moderate-sized berries, which ripen early in the autumn, and are, when in that stage, of a bright red colour. As a medium-growing tree for lawn or woodland this Thorn must not be passed over, as it is of vigorous constitution, and by no means particular in its requirements. The Scarlet-fruited Thorn can be readily raised from seeds, and though there are several varieties for which other modes of propagation are necessary, the common type is, as far as ornamental qualities are concerned, quite equal to any of them.—T.

Magnolia obovata.—This *Magnolia* may be looked upon as the last of the early flowering section, for the *Yulan* (*M. conspicua*), *M. Soulangeana*, and *M. stellata* are all past their best before the blossoms of this make their appearance. *M. obovata* does not attain to tree-like dimensions, its habit being more that of a large growing shrub, and it is very ornamental when in a flourishing condition. In colour the flowers are purple on the exterior, and whitish within, but they do not open sufficiently to show the inside of the bloom. The first of these early flowering *Magnolias* to open is *M. conspicua*, the Chinese Lily tree, closely followed by *M. Soulangeana*, which is supposed to be a hybrid between the *Yulan* and *M. obovata*. Its appearance and time of flowering would certainly suggest that such was its origin, for both in habit, colour of blooms, and time of blossoming, it is about midway between the two. In any selection of these early flowering *Magnolias* two kinds that ought certainly to be included are the small double-flowered *M. stellata* and the fine dark coloured kind, distributed a year or two ago by Messrs. Veitch under the name of *M. Soulangeana nigra*. The easiest of increase of all these *Magnolias* is *M. obovata*, and propagated from layers it is often used as a stock on which to graft the others. *M. obovata* is also known under the name of *M. purpurea*.—T.

SHORT NOTES.—TREES AND SHRUBS.

A new form of Butcher's Broom.—We learn from the *Revue Horticole* that a new form of this, producing two fruits instead of one, has been found by M. L. Planchon. If this new form will maintain its character it will certainly be a desirable acquisition to our shrubberies.

Pearl Bush (*Exochorda grandiflora*).—We have two large bushes of the larger form of this excellent plant growing and flowering freely in the open border; both plants are in exposed situations; they seem to adapt themselves to circumstances, and are at the present time covered with their lovely white flowers.—T. B. F.

The Broom.—I forward you sprays of the different coloured Brooms. We have them all growing in the shrubbery

borders backed up with Lilac and copper-leaved Beech. At this time of the year they have a very gay appearance.—THOS. B. FIELD, *Bridgenorth*.
* * * Very beautiful, and most effective at this season of the year.—Ed.

TREES AND SHRUBS IN BLOOM.

A COMPARATIVELY flowerless May has made the flowers of June more abundant than usual, and particularly among trees and shrubs, which have been so retarded, that we have Lilacs and Laburnum mingling with Thorns and other trees that in normal seasons succeed the flowering of earlier things. What with Rhododendrons, Azaleas, Brooms, Spiræas, Barberries, every well-planted shrubbery and plantation, after the first few days of summer, show a most lavish display of colour. The commoner trees and shrubs everybody knows, but there are many others that rarely find their way into ordinary gardens, simply because they are unknown or when planting time comes are forgotten or overlooked. The following are a few now in full bloom that should be remembered in autumn at planting time:—

WHITE ROSE BRAMBLE (*Rubus deliciosus*), one of the Brambles of the Rocky Mountain region, is a shrub of marvellous beauty and not half enough known, although it has been often written about in *THE GARDEN* and other papers. One would scarcely recognise it as a Bramble, as it is so very unlike the prickly bush with which the name Bramble is in our English minds associated. In fact, it is an insult to the shrub to call it a Bramble, for there is not even a Rose more beautiful. Those who have seen it once will not need a description of it, as one never forgets its chaste beauty and elegant growth. The flowers are similar in shape to those of the wild Rose, but much larger; they are white, sweetly scented, and borne on branches that hold themselves out in a most graceful way, particularly if the plant is growing against a wall and not nailed in too stidly. But it does not need a wall, as it is as hardy as any North American shrub; at the same time a wall could not possibly be more beautifully clothed than with this Bramble. Readers of *THE GARDEN* may remember Mr. Moon's delightful drawing of this shrub, published on October 9, 1880. It shows a spray of the shrub just as one may see it this week against a wall in the hardy plant garden at Kew. It is a pity that nurserymen do not give it more attention. I have just referred to the catalogues of half a dozen of the leading nurserymen, and no mention is made of it, yet there are lengthy disquisitions about plants that are worthless compared with this Bramble. If people would make a request for it at planting time, perhaps nurserymen would work up stocks.

PEARL BUSH (*Exochorda grandiflora*).—This is better known than the White Rose Bramble, and one may buy a respectable plant of it for eighteen pence. But in this case there is some misapprehension, because many regard it as a tender shrub, suitable only for a wall. This may be the case in the cold midland districts and further north, but it is unquestionably a hardy, fast-growing, and lovely shrub in the neighbourhood of London and south of it. It is the largest flowered of all the Spiræas (for, in fact, it is a Spiræa), and this week it is one of the most beautiful shrubs imaginable, as the tender green of its newly expanded foliage contrasts well with the long drooping spikes of snow-white blossoms. It grows into a large and densely rounded bush, and the shoots, being slender, droop slightly, and have not that stiff appearance that other shrubs (Mock Oranges, for instance) usually have. Like *Rubus deliciosus*, it is well adapted for a wall, although, as before remarked, it does not require protection. Such a shrub as this should not be confined to botanic gardens, or, as old writers used to say, "to gardens of the curious," but should be as familiar as Mock Oranges and Lilacs.

MEXICAN ORANGE BLOOM (*Choisya ternata*).—Another flower of the week, as in several places it is covered with fragrant white flowers. This is really a wall shrub about London, and even with wall protection cannot be considered hardy, as severe

winters, like the last, damage the plants considerably. There is a large specimen of it against an east wall at Kew that attracts attention to it by the fragrance of its myriads of white blossoms. There is not a better substitute for Orange Blossom than this Mexican *Choisya*, and no doubt its flowers have done duty many times for the genuine Orange Blossom. It is a shrub of the highest merit; its luxuriant evergreen foliage alone makes it valuable, and the fact that it can be forced into bloom in winter enhances its value. It is just the plant to place against a sunny wall of a house near a window.

JAMELIA AMERICANA is almost an unknown plant outside the botanical garden, although it has been in cultivation many years. It is a small-growing deciduous shrub, bearing at this season a profusion of small pure white flowers, and the leaves being whitish, the whole bush has a distinct appearance. There is a fine plant of it in full bloom at Kew planted with the Saxifrages, as it is a member of that family. It is perfectly hardy, and seems to thrive best when on raised rocky mounds.

NEVUSIA ALABAMENSIS, quite a newly-introduced North American shrub, is beginning to develop its true character at Kew, and already shows that it is not quite such a worthless plant as some considered when they saw it in a small state. I look upon it as a pleasing shrub when in flower, elegant in growth, and distinct from all others. Its flowers are not much individually, as they consist merely of a tassel-like tuft of stamens, but they are borne in such numbers that each spray has a feathery appearance. The colour is a greenish yellow, reminding one of some of the Meadow Rues. The finest plant I have seen of it is that now growing against an east wall. It is now in full bloom. Its hardiness is doubtful, but wall protection seems to be sufficient.

WHITE SPANISH BROOM (*Cytisus albus*) is everywhere a charming shrub this week, large bushes of it being like fountains of white spray. Nothing can be more graceful in growth than the White Broom, and its hardiness, suitability to every soil and aspect, renders it one of the very best hardy shrubs we have in gardens. Though it cannot be called uncommon, one wishes that it was more plentifully planted so as to relieve the monotony of Laurel, Privet, Barberry, and other common shrubs. The most effective place to plant the White Broom is at the point of a group of low Evergreens, so that the long wand-like shoots may overtop them and fall gracefully on all sides. Another beautiful way of planting it is in isolated masses on the lawn, and the purity of its flowers may be brought out by mixing with it a plant of the straw-coloured *C. præcox* or the bright yellow Broom (*C. scoparius*), as they generally flower together and harmonise well. If you have a dry bank where little else will grow clothe it with White Broom and double Gorse.

PORTUGUESE QUINCE (*Cydonia vulgaris lusitanica*) makes a beautiful lawn tree, and those who hesitate to plant Apples, Pears, Plums, and other orchard trees because they look out of place on lawns may plant this Quince, for though it is similar in character to the common garden Quince it is much more ornamental, having larger flowers and fruit and broader leaves. The flowers, which now are in full beauty, are cup-shaped, fully 2½ inches across, and of a blush-pink colour. This tree may be found in some fruit-tree nurseries, but it must be singled out from the common sort when in bloom, and the large flowers and broad foliage are characters sufficient to distinguish it. In some nurseries it is preferred as a stock for Pears on account of its more vigorous constitution. It is not such a productive fruit-bearer as the smaller-fruited common sort, and that is why it is not often seen.

W. GOLDRING.

Daphne Fioniana.—This is a very desirable evergreen species of *Daphne*, forming a compact, much-branched bush, a yard or so high, and thickly clothed with dark green Box-like leaves. At all seasons it forms a very ornamental evergreen shrub, and just now the terminal clusters of pretty pink blossoms

soms, with which the plant is thickly studded, are very attractive. Like those of most of its allies, the blooms of this are agreeably scented. This *Daphne* succeeds best in a cool stillish soil, and where slightly shaded from the full rays of the sun. Another species of *Daphne*, viz., *D. pontica*, is now at its best, and though the blossoms cannot claim to be showy (being of a greenish hue), yet their curious shape, the profusion in which they are borne, and their agreeable perfume, are all points in their favour. This kind will succeed as well as most shrubs under the drip of trees.—H. P.

TO THE EDITOR OF THE GARDEN.

SIR,—Mr. Miller uses strong language, and his attempt to justify his so doing is more creditable to his ingenuity than to his accuracy. Thus, he says that any statement that "most of the names are inventions" is "a downright and malignant falsehood." This is a question of fact, and is easily settled. On page 2 of Mr. Miller's book, the first full page, there are 117 names. Of these about half are translations, adaptations, or "inventions." Such, for example, are "Michaux's White Alder" for *Clethra Michauxii*; "Fetid Aloe" for *Aloe fetida*; "Panicled White Alder" for *Clethra paniculata*; and others. Better examples will be found under the headings *Crocus*, *Stonecrop*, *Starwort*, and the like. By interpolating two little words, Mr. Miller has given my general statement a personal application. "The names are no inventions of mine," he says. I never said they were. I said they were "inventions," and so they are.

Mr. Miller complains that I say the local names "seen largely taken from 'The Dictionary of English Plant-Names.'" This again is true; and he has even followed us in the mistake by which we make "Affadil" synonymous with "Daffodil." Mr. Miller is cautious in saying that "nearly all" the names "were taken from sources" open to both of us. It was to the names which were not taken from such sources that my remark referred. On page 1 of Mr. Miller's book are *Adderspit*, *Adder's Fern*, *Adder's-flower*, *Adder's-meat*, and *Ag-leaf*. Will Mr. Miller tell me where these can be found in print, save in our book—and his! Others, such as *Adam's Flannel* and *Adam's Spear*, are extracted by us from glossaries and out-of-the-way books. Of course, Mr. Miller may have himself consulted these at first-hand, but I am, I think, justified in doubting this.

I am quite prepared to go further into this question, but I do not wish to trespass unduly on your space. I will conclude with two remarks.

When Mr. Miller's book appeared (in 1885) it was noticed in the *Journal of Botany*, and a copy of the review was sent to Mr. Miller. So far as I know, it is not until now that he has noticed the charge of plagiarism therein made. If Mr. Miller will refer me to the sources whence he obtained the names *Adderspit*, *Adder's Fern*, *Adder's-flower*, *Adder's-meat*, *Ag-leaf*, *Ail-weed*, *Alpine*, *Amber* (sweet), and many more which I am ready to specify, I will modify or retract my charge. Until he does so, I repeat it with as much emphasis as possible; and I withdraw the word "seem," and say that the names of British plants "are" largely taken from the dictionary compiled by Mr. Holland and myself.

Mr. Miller considers our title inappropriate. He can hardly have forgotten, however, that he appropriated it for his own work, on the first page of which it still stands. Mr. Miller's book was also announced and advertised under our title—a mistake courteously remedied by the publisher as soon as his attention was called to it.—JAMES BRITTEN.

** It is very cool of Mr. Britten to say such names as "Michaux's White Alder" are "inventions." They are nothing of the kind! We may safely leave Mr. Miller to deal with Mr. Britten's answer to his charge, but his talk of plagiarism deserves a few words. Assuming for a moment it is true as regards such names as he cites, it is regrettable to see a man devoted to science, and a paid servant of the public in our National Museum, stoop to charge an author with plagiarism, as regards words as much the property of all as is the multiplication table. It may be necessary to state that Mr.

Miller's book gives the names of garden and cultivated plants, and, instead of "most of the names being inventions," as Mr. Britten unjustly asserts in the preface to his book, they are gathered from standard gardening books since these began to be published in England.—ED.

SOCIETIES AND EXHIBITIONS.

FLORISTS' TULIPS AT MANCHESTER.

THE Royal National Tulip Society held its Jubilee Exhibition at Old Trafford on June 1, and a far better exhibition than was generally expected resulted. By way of making it a jubilee celebration the prizes had been considerably augmented, and growers put forth every effort in order to neutralise as far as possible the effects of the late season, and to have as good a representation of flowers as possible. To those who are specially interested in the Tulip an exhibition of this character has very great attractions, and growers, large and small, gathered from all parts of the counties in which Tulips are grown, more especially Lancashire, Cheshire, and Yorkshire. Those who expected—judging from the character of the season—to see the Tulip poorly represented were agreeably surprised to find a large display, many of the flowers pure, well marked, and brightly coloured. To the outside public the florist's Tulip must be a puzzle, not being able to distinguish between feathered and flamed flowers, and not understanding that the pretty breeders are merely Tulips in the seedling and transitory state. But the growers scan them with real satisfaction, and discuss their merits warmly. The principal class was for twelve blooms, two feathered and two flamed in each class, of bizarres, roses, and byblomens, and the first prize was won by the Rev. F. D. Horner, Kirkby Lonsdale, who had the following in fine character: Bizarres, feathered—Commander and Royal Sovereign; bizarres, flamed—Sir Joseph Paxton and Orion; roses, feathered—Nanny Gibson and Annie McGregor; roses, flamed—Mabel and Mrs. Lea; byblomens, feathered—Friar Tuck and Mrs. Cooper; byblomens, flamed—Talisman and Duchess of Sutherland. Mr. James Thurston, Albany, Cardiff, was second, also with good blooms. The Rev. Mr. Horner also had the best six, Mr. Samuel Barlow, Stakehill House, Manchester, being second. Beside the foregoing classes there were several others for broken or rectified flowers. It is customary on these occasions to select the best feathered and the best flamed flowers in the show, and term them the premier blooms. The best feathered flower was a seedling byblomen, shown by Mr. Alderman Woolley, a noted grower of Stockport; the best flamed flower, bizarre Sir Joseph Paxton, shown by the Rev. F. D. Horner.

The pretty shaded and self-coloured breeder Tulips—representing the transitory state of the seedling before it rectifies—are always attractive, but it must not be supposed that the handsomest breeders in point of colour always break into the finest feathered or flamed flowers. A poor ugly breeder will sometimes be transformed into a broken flower of surpassing merit. The Rev. Mr. Horner also had the best six breeders, staging fine and clear blooms of bizarres Ariosto and Sir Joseph Paxton; roses Miss B. Coutts and Thomas Parker; byblomens Alice Grey and Glory of Stakehill; Mr. J. H. Wood, of Royston, was second. The best breeder Tulip, selected as the premier bloom, was bizarre William Lea, shown by Mr. R. Woolfenden.

The Tulip season this year is one of the latest known for some time past. One of the most popular shows in Cheshire is fixed for June 17, four days later than any previous fixture; in 1811 this exhibition was held on May 21.

A late season.—A Covent Garden salesman said, the other day, "we are three weeks late," and I doubt if that statement much exaggerates the tardiness of the season. I am always able to accurately gauge the forwardness of the season by our

Strawberries in cold frames. In a general way the first fruit is ripe in them in the last week in May. This year we shall not gather from them by the middle of June, unless we get some very hot weather. Some years ago I remember gathering ripe Strawberries in the open on May 20. This year the earliest berries are only just set. It will be far into July before the field crops can come in. I have no doubt that there will be a much less quantity of soft fruit come into Covent Garden in June this year than has been the case for a long period. The Strawberry crop will this year be very heavy, and the early gatherings will probably sell at good prices, but for the main bulk, growers must be prepared for a low figure. Last year the price per ton for fruit for preserving was a third lower than in preceding years, which was to be expected, seeing the enormous breadths that have been planted within the last few years.—J. C. B.

RAIDS ON WILD FLOWERS.

I DID not wish to convey the idea when I first wrote on this subject that I did not think our wild flowers were raided upon by the public when visiting those places of public resort where no kind of supervision was exercised, because I have seen such things myself and protested against them in THE GARDEN long ago, but I do say that when such raids are made and such wholesale destruction worked in private parks and pleasure grounds as has lately been described in THE GARDEN, those responsible for the care of such places are more to blame than the visitors. Such vandalism can be prevented easily, and such complaints as we have lately read should not be accepted as an excuse in any case for depriving the public of the privilege given by many proprietors, and enjoyed by visitors. Only those who are in the habit of seeing many people from the towns enjoying themselves under such circumstances can estimate the value of the boon to them. During the past Whit week the parks here have been crowded every day by visitors from Manchester, Sheffield, and other Yorkshire towns without a single case of misbehaviour being reported. Of course, it is understood that injury to trees or flowers is not permitted. Short of that, the people are encouraged to enjoy themselves. I fear some of your correspondents have exaggerated the matter. When I read "D. T. F.'s" account of his "enormous" attempt at wild gardening, and of its defeat by those who stole the plants by cartfuls, &c., I wondered what the proprietors of such parks as Chatsworth, and gardens like those at Belvoir and the like, would think, for I believe no other serious attempt at wild gardening has ever been defeated in the same lamentable manner.—J. S. W.

** This is all we can publish on the matter. The nuisance, where it exists, should be stopped in any way that may be most effective in the locality. It would be a great loss to all if the charms of our beautiful private places were destroyed in the brutal way described. Even in public gardens and parks this destruction has to be prevented, otherwise they would soon arrive at the desert state.—ED.

Rhododendron Mrs Isaac Davies.—We send trusses of our new hardy Rhododendron, for which we can at least claim the merit of novelty. The foliage is handsome, the plant of bushy habit, and, in common with most light coloured Rhododendrons, is very hardy. The Rhododendrons are blooming well with us this year.—MESSRS ISAAC DAVIES AND SON, *Oskivik, Lancashire.*

Very distinct, compact truss of smallish flowers, the upper petals richly blotched with deep purplish crimson on a pale rose ground.—ED.

Names of plants.—A. W. W., *White Green.*—The *Maslevilla* numbers were loose, and the flowers much shrivelled; the large flower appears to be *M. an dibislineata*; a good var. of *Odontoglossum Lindleyanum*; 4, *O. Alexandrar.*—W. B.—1, *Saxifraga longifolia*; 2, *Papaver nudicaule*; 3, *Asplenium Adiantum-nigrum.*—*Habitat.*—1, *Dendrobium Parishii*; 2, *Cypripedium concolor*; 3, *Colax jugosus.*—G. Lanoor.—*Virus pinnatifida*—K C—*Primula sikkimensis.*—M., *Southampton.*—*Cycantium phacum*, *Spiraea hypericifolia.*—J. H. P.—*Astina triloba.*—J., *Southampton.*—1, *Odontoglossum hystrix*; 2, *Bolbophyllum Lobbii*; 3, *Ornithidium coccineum*; 4, *Celogyne Massangana.*—J. E., *Sheffield.*—1, *Braema insignis*; 2, *Menicium simplex*; 3, *Didymopanax humulata*; 4, *Gymnogramma microphylla.*—G. W., *Leeds.*—1, *Gymnogramma Pearcei*; 2, *Notholaena leavis*; 3, *Diplazium lanceum.*—L. A. J.—*Scilla campanulata maxima*; send another specimen of the other plant.—Acon.—*The Snowy Mespilus* (*Amelanchier Botryanthum*).

WOODS & FORESTS.

“YORKSHIREMAN.”

THE TUFTED CYPRESS.

(CUPRESSUS TORULOSA.)

HAVING had to remove, but, I must add, rather reluctantly, an unusually fine specimen of the above tree, I was much impressed with the hard, deep purplish brown and beautifully grained wood, as well as the large size to which the tree had attained in thirty-five years. The specimen under consideration was one of two that had been planted for garden ornamentation, and it had attained to a height of 13 feet, with a straight and well-branched stem that girthed just 3 feet 1 inch at a couple of yards from the ground—no bad dimensions for a Cypress of thirty-five years' growth.

Few trees are better adapted for planting where space is rather confined than the tree in question, and being in every sense of the word highly ornamental, is thus of great value for lawn or garden decoration; indeed, in the whole range of Cypresses, there is no other so beautiful as the above—its easy, though columnar, habit of growth, slender branchlets, and bright glaucous foliage being all desirable acquisitions that are, perhaps, not so nicely blended in any other member of the family to which it belongs.

The tufted Cypress is usually classed as a semi-hardy tree, and one to be colddled in some shady, warm nook of our gardens and grounds. Although a few specimens did succumb to the intense frost of the winters of 1860-61 and 1866-67, yet many remained uninjured, and in nearly every instance where trees were killed outright, the cause might be traced to the unsuitable positions in which they were placed, low-lying and well-sheltered places being chosen in which to place this lover of high and dry ground and a cool, breezy situation. Throughout Scotland generally, but particularly along the western coast, this tree has, after a fair and impartial trial extending over a period of nearly forty years, been found to be well suited for planting, but particularly in high-lying ground, and generally away from the sea coast. In Perthshire I have seen some grand specimens of this Cypress, the clear, bracing atmosphere and intense winter cold seeming, from their healthy appearance, to indicate that under such conditions they were quite at home. In Carnarvonshire we have many trees 35 feet high and upwards, and I cannot remember during my sojourn here having seen a single plant either killed outright or injured by frost. In the “Pinetum Britannicum” it is stated regarding this Cypress that at Eastnor Castle, in Herefordshire, those at 300 feet to 350 feet above sea-level were killed, while on the higher ground, 550 feet to 600 feet above the sea, they were only slightly injured.

In planting *Cupressus torulosa* it may therefore be well to bear in mind not to place it in low-lying damp ground and where it is too much sheltered, for experience has proved pretty clearly that this handsome tree succeeds best where the wind is allowed to play freely around it, and, as a rule, in high-lying inland situations. Soil would not seem to be a factor of great moment in the cultivation of this Cypress, at least judging from the specimens here, for they are growing in stiff loam nearly approaching clay, in good loam on an open sandy subsoil, and in almost pure gravel, the two latter classes, however, suiting it best and producing the largest and healthiest trees. The branches, which are thickly produced, have a decided upward tendency, but are, nevertheless, not painfully so, as is the case with some Conifers, for the tufted branchlets, with their easy-arranged foliage, deprive it entirely of the fastigate appearance that characterises not a few of our Conifers. The cones, which are produced in great abundance and in dense clusters, are about an inch long, globular, and composed of about ten scales. There are usually seventy seeds in each cone. As before stated, the timber is hard, close grained, and fibrous, of a pleasing purplish yellow colour, and very fragrant, the latter being noticeable even when felling the trees.

This tree has been designated by some writers the Bhotan Cypress, but it is open to question if it deserves the name, for Dr. Hooker states that it is a rare plant in the Himalayas, and is apparently confined to the western side of the range. It was first discovered by Hamilton in 1802, and introduced by Dr. Wallich in 1821.

Seeds have been freely produced on the trees at Penrhyn and young plants successfully raised, the latter requiring neither great patience nor an extra amount of attention.

A. D. WEBSTER.

PLANTING FOR UTILITY AND ORNAMENT.

I HAVE always considered it practicable to plant a permanent undergrowth of evergreen and deciduous trees and shrubs to serve either as screens near or away from a mansion or cover for game, and at the same time to ensure a free growth of profitable and ornamental timber.

In one instance I have planted in masses what I intended to be the permanent trees which were to form a screen to shut out some unsightly buildings. The kinds of trees planted for the purpose were chiefly Oaks, Spanish Chestnuts, and Elms. Then others of the same kinds, but of smaller size, were planted between them by way of filling up the spaces until the principal trees begin to extend their branches, when the supernumerary trees are to be taken out in two, three, or four years to plant again as single trees, or in groups, hedge-rows, or for any other purpose for which they may be wanted, as they will be suitably prepared for such purposes, otherwise they must be cut down or taken out before they injure the permanent trees. The other spaces should be filled up with Beech and Hornbeam, which, when headed down, generally retain their foliage through the winter months, when such thick cover is most wanted. Such plants for undergrowth I take care to divest of their leading upright shoots at from 4 feet to 6 feet or 7 feet high, according to their appearance and effect with the side branches of the intended permanent trees. Divesting them of their upright aspiring shoots prevents them from injuring the permanent trees, and increases their lateral or side branches, so as to keep up a permanent undergrowth. This work should be attended to for a few years to prevent them acquiring fresh leaders, which they are naturally inclined to do.

At the base of the permanent trees I planted young Hollies, either common or variegated, for future effect, at from 1 foot to 2 feet from the stem, with the head leaning towards it, to allow for the increase of the trunk or stem, as well as to form a surer mark than any other I could think of to know the permanent trees by. Then round the outsides of the belt and occasionally in the interior, I planted Spruce and Silver Firs and Scotch Pines, each kind by themselves in groups or masses, as it were; the Firs being from 1 foot to 7 feet in height, taking special care to shorten the leading upright shoot, or break out the central leading bud of the upright shoot, at the desired height; also to shorten or break out the leading bud of the side branches, where necessary, to thicken the growth, and prevent it getting out of bounds and destroying or injuring the fences. Scotch Pines should be planted principally at or near the outside, as they do not endure under the shade so long as the Spruce and Silver Firs. In front of this belt, viz., the side most in view, were planted various kinds of evergreen, deciduous, and variegated dwarf flowering trees and shrubs: at least to be kept dwarf so as not to injure the effect of the permanent forest trees in the background, as well as more effectually to ensure the main object, an effectual permanent blind, not forgetting embellishment as well. Although I have recommended Beech and Hornbeam for under-cover, I would prefer common Hollies, common Laurels, Rhododendrons, or other suitable Evergreens, which will endure under the drip and shade of other trees, but they are of such slow growth at first, and are, besides, dearer, and not so easily procured as the Beech and Hornbeam. At any rate, the Evergreens should be planted at the first making of the planta-

tions, and, as they get up, the Beech and Hornbeam could be removed if thought desirable; but in each case attention must be, for several years, regularly paid to divesting them of their aspiring shoots, and occasionally shortening some of the side branches to prevent too much straggling and to ensure the permanent undergrowth. I will just observe that Beech and Hornbeam are best adapted, in distant high exposed situations, for permanent undergrowth in narrow belts or clumps, and Evergreens nearer home in more sheltered places.

By following up this plan for a few years, we can ensure a permanent close and thick undergrowth of evergreen or deciduous trees and shrubs, with the most beautiful, picturesque, and profitable forest trees, instead of those unsightly naked plantations, open at bottom, with nearly valueless timber trees, so frequently to be seen; which plantations, with a very little trouble or expense, might be made both profitable and ornamental at the same time. But, alas! gentlemen do not see this; or, at least, they will not pursue it, too often, I fear, from the causes I have previously hinted at.

I could say much more on this subject, and on that of pruning and training hedgerow timber trees, but more particularly single evergreen trees, or masses of evergreen trees in noblemen's or gentlemen's parks, with accompanying undergrowth for shelter and protection to the trees—such parks being generally very deficient in these respects, and having rather a dreary effect in winter without these accompanying embellishments, when there are hundreds of acres ornamented with only deciduous trees.

W. B.

SOIL EXHAUSTION BY TREE ROOTS.

ONE would suppose it unnecessary to point to the fact that it is essential to have trees well furnished with strong and healthy branches to the ground, whether planted as shelter-belts, screens, or specimens on lawns; instead of this, however, they are too often allowed to remain with their roots engaged in a life and death effort to extract the requisite food and water from the soil, which, through having had to feed three times the number it was capable of sustaining, in the end becomes so exhausted that the whole of the lower branches perish and become not alone unsightly, but absolutely useless for the purpose intended. And if we come to the internal part of the grounds, where this very common course is followed, the condition of the trees is usually much the same as that of those on the outer portion, often not showing a single fairly-grown example that gives promise of continuing in a healthy state to anything approaching its allotted time; such trees, owing to their position, are often held in high estimation by their owners, who, by their unwillingness to part with any, allow them to remain in a state that will inevitably cause the destruction of the whole. They seem unable to see that the earth can no more sustain two plants where one requires all the nutriment present than it can feed two animals confined on a space only large enough for one. The two cases are analogous; but trees do not show the positive effects of starvation so soon as animals do. There can be no question that half of any given number of trees, especially when occupying positions from which they can ill be spared, are greatly to be preferred to double the quantity existing under conditions wherein their food requirements are so far insufficient as to lead to their gradual, but certain destruction.

Nothing less than sufficient room for the branches of a tree from infancy, and a corresponding space of ground unoccupied by the roots of other trees, can secure a healthy condition for the full period of its existence, yet it is surprising the efforts which trees are capable of making in order to repair the injuries which they have suffered when the causes by which they have been affected are removed, and in most cases even where they give unmistakable signs of suffering from insufficient food through overcrowding. If the number be reduced so as to afford those remaining a chance of succeeding, they very soon show the benefit done them; and by these means, which rarely fail, unless in cases in which

decay has gone too far, large numbers of trees that have got past their best would be so far invigorated as to attain and keep in fair condition for many years. It should not be forgotten that of trees in pleasure grounds, such as those under consideration, a great portion have their roots wholly in soil, the Grass being kept continuously mown without anything to counterbalance the impoverishing effects until the whole is as poor as it is possible for it to become, and with no opportunity of much being done that would strengthen their roots; if they, in addition, occupy the ground in too close proximity to each other, the evil is very much intensified.

Where shrubs are grown over the roots of the trees new soil and manure in quantities sufficient to afford a good deal of assistance can be, and frequently are, applied with considerable effect, but the shrubs with their roots near the top are the first to take advantage of the manure and derive the greatest benefit, especially in the case of many species of deciduous trees. It is to judicious thinning that I would point as the most effectual means for the preservation of trees in the places I have alluded to. The subject is worth consideration.

T. B.

PRUNING FOREST TREES.

GREAT difference of opinion prevails as to the necessity for pruning forest trees and the season at which such operations should be carried out. But undoubtedly the weight of authority is favourable to early summer pruning. The month of June is strongly recommended, because at that time the wounds heal up much quicker than during July or August, when the motion of the sap becomes slower. A standing rule with the pruner that no wound remains exposed to the action of the atmosphere for a longer period than one year. If the aim of the owner of woodlands was confined to the production of the greatest amount of wood upon a given area in the shortest possible time, it is questionable whether pruning of any kind should be executed; for every branch cut away from a tree lessens the quantity of foliage presented to the action of the sun and the atmosphere, and therefore decreases the absorption of carbonic acid gas and the formation of wood, of which carbon is the main constituent. But where the object in view is the growth of straight, lengthy, clean, and sound timber, thinning and pruning must commence soon after planting and continue until the trees attain considerable proportions. By thick planting, early thinning, and careful stopping of rambling shoots or rival leaders, pruning will seldom be necessary except in the removal of injured branches. But as the growth of a tree is slow, and he who plants seldom lives to train up his trees to maturity, pruning in an advanced stage of their growth is often necessary in order to lessen the evils resulting from early neglect.

Trees differ so much in habit and in their rapidity of growth, and are so largely dependent upon the soil and situation in which they are placed, that it is impossible to lay down any precise rules for their management in this respect. Those trees meant to form large and good timber should never at any stage of their growth be suffered to become too much crowded, nor over-topped or whipped by their nurses, and as they rise they should be allowed sufficient space to enable them to develop well-proportioned heads, equal in length to form from one-third to one-half the height of the entire tree. It should also be borne in mind that by preserving a complete canopy of foliage overhead the moisture is retained in the soil, the stems rise rapidly, and the formation of side branches is retained.

The advantages of early pruning are nowhere more observable than in young plantations of Oak and Spanish Chestnut. Two years after planting it is no uncommon occurrence to find a considerable number of the young trees hide-bound and becoming distorted in their growth. Such, if left to themselves, seldom or never attain to the size of timber trees. But if cut over with a clean section within 2 inches of the ground they will push forward vigorously during the following spring and summer.

By rubbing off all but two of the strongest shoots in June or July, and allowing these to grow on together until the following March, and then cutting out the weaker of the two, and afterwards keeping the other single upon the stub, a vigorous growth may be ensured, which will in a few years far exceed that of the uncut trees. A most remarkable instance of this is mentioned by Forsyth, who, the second year after planting a bed of Oaks, headed down one-half and left the other to grow naturally. In giving an account of their progress a few years afterwards, he states that one of the plants thus cut over was 18 feet high and 15 inches in circumference at 6 inches from the ground, while the largest of the uncut ones was only 5½ feet high and about 4 inches in circumference.

But, while recommending the early and careful pruning of forest trees, I would not be considered an advocate of the excessive lopping and pruning introduced by Pontey, and so ruthlessly carried on by his successors, who looked upon and spoke of the branches of trees as being merely "robbers of the stems." To produce lengthy timber, every branch which threatens to rival the leader should be shortened. By adopting this method instead of cutting away the branch entirely the trunk is strengthened by the sap being detained in its descent. Timely attention will obviate the necessity for heavy prunings at any stage of a tree's growth. The pruner should, however, be conversant with vegetable physiology, otherwise that twilight of uncertainty in which all his operations are performed may lead him to commit grave errors. In close plantations the destruction of the lower branches is really caused by the exclusion of light, and the result is generally unsoundness of stem. This is found to be the case so extensively in Canada and other large timber-producing countries, that a very small proportion of the trees grown under such circumstances is fit for exportation.

The whole art of pruning and training timber trees lies in adopting a proper mean between the two extremes of cutting away the branches of a tree so as to give it the appearance of a mere May-pole in the one case and that of a dense spreading bush in the other. A severe mutilation of the head of any tree must for a long time paralyse the action of its roots, and on this account the heavy pruning of neglected trees, if undertaken at all, should be extended over two or three seasons. Deciduous trees will require the most careful training in order to produce sound timber. As considerable difficulty is experienced in pruning trees of a resinous kind without injury to their growth, it becomes the more necessary to plant and rear them in close order. The lower branches under these circumstances are soon killed back, and may be removed so that the longitudinal structure of the bole is but little injured, as, by the early destruction of the laterals, the superincumbent layers of wood are entirely free from knots. Thus it happens that Fir timber grown in close plantations, where the early removal of the dead, bolt-like insertions left by the dead branches is attended to, becomes the most valuable, while single trees, from their coarseness of grain and abundance of large knots, are almost worthless to the builder. It is also found that Ash grown in close plantations becomes much tougher and clearer in the grain.

In exposed situations both the pruning and thinning of trees should be much lighter around those margins of plantations which face the prevailing high winds of the district. By too close packing it often happens that only the face of the very outermost trees are clothed with foliage, so that any injury to one of these admits the destructive winds. This may be guarded against by a judicious early thinning of such margins, so as to secure a belt of low-branched trees.

A. J. B.

Preserving timber.—Among methods which have been brought forward for the preservation of bridge timber and railroad ties is one which subjects the finished timber to an adequate dry heat, and then immerses it in a hot bath composed of certain proportions of asphalt and carbolic acid. The effect of this treatment is that, on cooling, the

solvent of the asphalt evaporates, leaving a skin of coating of asphalt on the surface of the wood, which resists water and keeps the antiseptic material fixed securely within the pores of the wood. The exterior of the wood, on the completion of this process, presents a smooth and dark surface requiring no paint.

The Birch is capable of withstanding a much greater degree of cold than any other tree. In the Old World its northern limit is 71° upon the west, and 63° upon the east coast; in America its northern limit is 64° upon the west, and 58° upon the east. In Germany, the highest elevation at which it is found is 5200 feet above the level of the sea; in Sweden at 3900 feet; and in Lapland at 1722 feet. It is worthy of remark that this tree decreases in size not only as it advances towards the north, but also as it proceeds southwards beyond the limits of its native region. It attains its highest perfection and greatest height in Germany and Southern Sweden.

Planting waste land.—It is an undisputed fact that the planting of waste land with trees would be the means of bestowing a great benefit on this country in various ways. There are millions of acres of waste and almost worthless land, so far as agriculture is concerned, that could be made most profitable plantations, and the owners of it should not allow the present favourable opportunity to pass without adding largely to the area under forest trees upon their estates. The low price of labour, and the ease with which any amount of it can be obtained at the present time, should be a strong inducement to all enterprising landowners to engage at once in planting, upon a judicious and well-arranged plan, all the waste land upon which trees will grow, and other properly chosen ground, upon their estates. A safer investment of money, or a more profitable one, cannot easily be found in these times, besides the great benefits immediately derived by the country, through the employment of the present abundant supply of surplus labour. Estate improvements of every kind can now be carried out in the most economical manner, and those who employ the greatest amount of labour at the present cheap rate will reap the greatest reward at a future and not far distant time, when trade and wages regain their natural buoyancy.

Riven v. sawn Oak fence.—It does not say much for the observation of the bulk of the people if, as "Yorkshireman" says (p. 523), "it is not generally known that riven stakes are stronger than sawn ones." Of course, it is this fact which leads to the use of cleft wood for spokes, hammer shafts, and similar things. What I cannot understand is the statement that only unsaleable Oak is used. With us, wood that comes under this denomination consists of unsound or very rough and knotty stuff, and to give the impression that this answers well for cleaving into fencing stakes is an error. At any rate, some further explanation is necessary. It is true that a certain class of posts or stakes may be cleft from the straightest of Oak tops, but not such as "Yorkshireman" indicates on p. 523. For splitting out these 3-inch by 2-inch stakes, small Oak is certainly the most suitable material, but it must be sound and fairly clean at the grain, and therefore, in the ordinary acceptance, cannot be classed as unsaleable. I wish a few more particulars had been given as to the use of these stakes, viz., the height of the fence and the distance from stake to stake, also how far they should be driven into the soil. This last point, I know, would vary according to the subsoil, but for the remarks to be of any real value, each of these things should be commented upon. I have but little faith in a fence erected wholly or nearly so of driven stakes or posts unsupported, if it exceeds a height of from 3 feet to 4 feet, and is likely to be subjected to any considerable lateral pressure. In fences of this class it is of little use to attempt to have uniformity, as if posts of varying size are used, appearance does not much matter. What I suggest, therefore, is that every third post or stake should be stouter, and instead of being driven, have a flat end and a hole dug for it, and rammed up in the ordinary way.—D. J. YEO.

No. 813. SATURDAY, June 18, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakspeare.*

FLOWERS IN THE HOUSE.

Under this head we propose, during the present season of flowers, to notice things, from whatever department, that are pretty and useful for the house.

FEATHERED PINK, BLUSHING BRIDE.—A seedling raised at Temple Hill, wonderfully floriferous and perfumed. The colour of pink satin.—W. B. HARTLAND, *Cork.*

HAWTHORN BLOSSOM.—One loves this for its beauty in tree, in hedgerow, but the flowers reveal their charms in other ways when brought near the eye on the table—best perhaps by themselves.

COTTON GRASS (*Eriophorum*).—Would the floral workers with immortelle wreaths do anything with this from the bogs and marshes of the County Cork? It should be gathered now. It would dye beautifully.—W. B. HARTLAND, *Cork.*

COLUMBINES.—I send you a few Columbines for the editor's table. I think they will about match any I have ever seen. The "principle of selection" for some years is bringing about a satisfactory result.—A. RAWSON.

** A very fine selection.—Ed.

MRS. SINKINS WHITE CLOVE PINK.—Here is the plant to "cut and come again" from all the summer. By pinching the first attempt at bloom on young plants, one can enjoy an August supply in quantity. In the autumn a bed of this Pink perfumes the air in the evenings like *Matthiola bicornis*.—W. B. HARTLAND, *Cork.*

SIX KINDS OF DOUBLE ROCKET.—Six forms of these fragrant old plants from the Rev. Denis Knox, Virginia Rectory, Ireland. We are glad to see them well grown, and their fine fragrance fills the house. The kinds are the French white, pale lilac, old white, pale blush, Eglington white, and old lilac. We thank Mr. Knox for reminding us all of the existence of these forms of an old favourite.

RHODODENDRON CINNABARINUM.—I send some trusses of *R. cinnabarinum*, which you will see vary considerably on different plants; this is also quite hardy here, and flowers very freely as a rule, but this year they are not so full as usual. The plants grow well, and are so distinct and beautiful as to merit a place in the most select garden.—R. GILL, *Tremough, Cornwall.*

** Densely flowered branches of this striking *Rhododendron*.—Ed.

FOR the editor's table I send *Paeonia albiflora* from a clump in the pure sunshine, now bearing thirty flowers and buds; no plant in the garden is finer in port and blossom. *Iris susiana* is also in flower after several trials to grow it here. *Ornithogalum arabicum* has also flowered well in pots in the greenhouse, and also on a sunny outdoor border. Its stary blossoms in a dense mass, each flower having a black

pearly ovary in the centre, are very distinct and effective. An old plant not easily and permanently grown. Irises are glorious; *Victorine*, *Shakespeare*, *americana*, *pallida*, *dalmatica*, *Gracchus*, *Billiotti*, *atro-purpurea*, *florentina*, and the pure white form called *Princess of Wales*, are all good. The Spanish varieties are also opening, and the oriental Poppies are gorgeous in the hot sun.—F. W. B., *Trin. Coll. Bot. Gardens, Dublin.*

WHITE PEONIES are grand now; such noble, sweet-scented blooms for ladies' wear. One flower, indeed, quite sufficient.—W. B. HARTLAND, *Cork.*

** Mr. Hartland sends a very pretty one. This magnificent family of plants is no longer in danger of being neglected, as we see large areas being cultivated about London.—Ed.

WHITE ROCKETS.—I send you some spikes of *White Rocket*; how beautiful, and such a perfume.—W. B. HARTLAND, *Cork.*

** Some of the best *White Rockets* we have ever seen were grown in Ireland, and we hope the quality will be kept up. What Mr. Hartland sends us is, we think, what is called the French white, and not the true double white.—Ed.

THE JAPAN PRIMROSE.—I send you some bloom spikes of *Primula japonica* grown out of doors from seed sown three years ago. Is it common for *P. japonica* to show so much variety from seed? if so, what about the possibility of a yellow *P. japonica*?—ARTHUR THOS. BOWLES.

** Diverse and fine varieties of this plant, which we believe is found to do very well in a naturalised condition. Many things are possible that are not desirable, and we have such good yellow Primroses, that perhaps an attempt to get a yellow Japan Primrose would be a mistake.—Ed.

SNOW IN SUMMER.—This is the name Mr. Hartland uses for *Helichrysum rosmarinifolium*, and not at all a bad one. A most excellent plant in full flower. He says: "We have this beautiful carpet of *Snow in Summer* covering the walls in southern positions. A great beauty, the sprays cut in a green state, the stems dipped in camphorated spirit and tied up in air-tight bags in a cool, dry place, may be enjoyed in perfection at Christmas, and in a most preserved state. It is one of the best shrubs extant for summer cutting, where white flowers have to be gathered for funerals. What a plant to grow in warm countries! I can grow it to great perfection, as you see per samples sent herewith."

TUFTED PANSIES.—Messrs. Dickson, of Waterloo Place, Edinburgh, send us some delightful tufted Pansies, which we are never tired of admiring. There is a very pretty white, *The Bride*, a soft creamy white, with a good yellow eye; *Ariel*, a lavender, with a whitish eye; *Formosa*, a very pretty lavender-blue, with purple eye. We do not like Latin names for these varieties. They should be christened with some pretty, simple name. *Columbine* is a very delicately marked white and lilac, with a pretty name. *Pantaloons*, purplish, with upper petals lighter; *Duke of Albany*, small, a very pleasing purple. We hope Messrs. Dickson will make a speciality of these lovely Violets, and have varieties with small flowers as well as with large. Some of the small-flowered kinds we find charming and most effective in their

profusion of bloom. *Souvenir* is a fine blue. All Pansies should have pretty names, like *Ariel*; not *rigmarole* or foreign names.

BEDDING PANSIES FROM KILDARE.—I send you a small plant each of a dozen kinds of bedding Pansies taken out of our spring bedding arrangement, where they are used in lines and masses. They have suffered very much from drought, as we could not water them, and there are cracks in the beds that you could put your foot in out of sight. Four and a half inches of rain is our total for the past four months. Hardy plants are having a hard time of it. We grow about fifty varieties of Pansies for spring bedding.—FRED. BEDFORD, *Straffan House.*

** They look very fresh, considering how much they have suffered. Too much attention cannot be given to these bedding Pansies, or tufted Pansies, if the name be preferred. We are under the impression that the raisers of them would do well to select the more delicate and varied colours in addition to the decided colours that are now popular.—Ed.

HARDY BULBS IN LONDON GARDEN.—The flowers sent herewith are all grown in the open air, and have had at no time any shelter whatever, not even a hand-glass. Will you kindly name the *Paneratium*; it came with some mixed bulbs? *Iris tectorum* has now done well with me for three years; what a very beautiful flower it is. *Ixiolirions* I have given up growing in pots, they do better in the open. *Camassias* are now going off, but have been very fine. Among choice *Narcissi* this spring, I thought *William Goldring* one of the finest, and the double *Narcissus cernuus* very pretty. The following note on *Eremurus robustus* may be of interest. In June, 1885, three plants planted the previous autumn bloomed very finely. One of them was then figured in *THE GARDEN*. Last year they did not bloom, throwing up only fine masses of leaves. This year, however, they have thrown up splendid spikes, far finer than in 1885, and are just about to bloom. I protected them by glass at the time of the heavy snow in the spring of last year. This year they have been left entirely to themselves. What glorious hardy plants they are.—H. STUART-WORTLEY (Colonel), *Rosslyn House, London.*

** The *Paneratium* is *P. illyricum*.—Ed.

ENGLISH NAMES FOR PLANTS.

PERMIT me as a foreigner to come forward in this matter, and to lay before your intelligent readers the following case: A Mexican nurseryman conversant with the English language, but not with English plant names, offers to one of his London colleagues *Mayflower* at 30s. per dozen; in consequence the English nurseryman would reply that he could not make any use of the offer, as *Mayflowers* could be bought in the London market at 2s. per dozen, he—good man—having no idea that with the expression *Mayflower* was meant *Flor de Mayo*—*Laelia majalis*. It is all very well that plants having become popular should have a popular name, but if the matter be pushed too far, only endless confusion would be the result. Although England takes the foremost rank in horticultural and botanical matters, yet it cannot be denied that another nation also has the right to call plants after its own fashion, and if an English horticulturist calls *Korolkowia Sewerzowi* a rather barbarous name, what would be the consequence if he had to do with the same plant bearing a Russian national name? If any of the large English trading firms would offer plants or seeds only under their English names, they would soon find out a decrease in business. I take this matter from an international standpoint; horticulture and science are international, and to a great

nation the widest views in that direction are the most benefiting and the most honourable.—MAX LEICHTLIN, *Baden-Baden*.

* * * *The question raised by us is that of English names for English-speaking people, one apart from the international convenience referred to above. For example, the French people use French names for plants: it does not prevent them using the Latin ones when they want them.*—ED.

CHRYSANTHEMUMS.

E. MOLYNEUX.

CONTINUE the potting of the plants into their flowering pots, for whatever purpose they are grown, as fast as the pots in which they are now growing are filled with roots. Neglect of this will entail serious disappointment later on, by a partial loss of the lower leaves. Stand the plants as fast as they are potted in a sheltered situation. When the weather is such and circumstances admit the plants being placed in their summer quarters, preparations should be made first for their reception, particularly those plants intended to be grown for the production of large blooms, which necessitate a tall growth requiring special means to keep the plants in their proper upright condition. If such a position as I named in a former issue, viz., one row on the side of a path running east and west, or one row on each side of a broad path running north and south be selected, it is better to stand the pots just within the border or quite clear of the path, as the continual watering with liquid manure is apt to disfigure the gravel. In such a case, boards whereon to stand the pots should be used, as a sufficient quantity of ashes cannot be placed in such a temporary position to prevent the ingress of worms through the soil and ashes. Where ashes are used, the foundation should consist of a thick layer of broken bricks or clinkers for a free drainage of the water as it passes through the pots. Bricks, two to each plant, are sometimes used, and where plentiful answer well. Provision must be made for securing the plants against strong winds. This is best done by erecting a trellis-work, to which the plants can be fastened. The strongest and neatest method of effecting this is that of making a permanent structure of iron standards. The end standards should be 1½ inches square, and be kept in position with iron supports 1 inch square; the intermediate posts may be flat iron 1½ inches wide and three-eighths thick. To these connect stout galvanised wire, to which a coat of paint has been given, to prevent damage to the tender shoots.

Such contrivances are sometimes objectionable as permanent objects; and if so they can be easily taken down and stored away if the wires are fastened with bolts and nuts. In some districts cultivators have at command an unlimited number of stakes of various lengths and thicknesses; a framework of these can be put up which is strong, cheap, and easily taken down and stored during winter. The upright stakes should be of sufficient stoutness to prevent the plants swaying about, and be placed at such a distance as their strength and the length of the cross rails necessitate. For the tallest plants, three cross rails are necessary, while for the moderately tall-growing sorts two are enough, and one for the shortest plants. Some growers stretch twine from post to post instead of the rails, but this soon becomes slack by exposure to the weather, and is not sufficiently firm to prevent the plants rocking to and fro. Place to each plant a stake of the same height

as that to which the plants will grow. When the plants are placed in position, the stakes are tied to the cross-rails, thus making all secure. The branches produced at the first break are spread out, the centre one being tied to the tall stake, and the others to small temporary stakes fastened from one cross-rail to the one above, thus giving equal light and space to each of the three branches; by placing the pots 1 foot 6 inches apart ample space is allowed between each. When the plants have to be arranged all together, the taller plants must be arranged at the back and the dwarfer in front; thus each line is not interfered with by the shade from the front rows, and the tall growing kinds do not interfere with those of dwarf habit. A knowledge of the relative heights of each variety is necessary to effect this arrangement, and for the guidance of the inexperienced I append a list of names with the height in feet, which differ somewhat in accordance with the treatment and the method under which the plants are grown. The heights given are based upon the idea that the plants are grown to one stem until they naturally break into other growths, and not upon the stopping principle.

Under the last-named system the plants are generally not so tall; therefore this circumstance must be taken into account when allotting out the space for each. The tall growth made by some varieties goes a long way towards condemning the method practised for the production of large blooms. If equally good flowers could be produced under any other system of culture, it would indeed be a boon in many ways, but my experience proves that it is not possible. Almost every sort has something special about it, either in the habit of growth, colour of the wood and leaves, or in the formation of the flower buds. To the inexperienced in these matters it is a good plan to arrange all the plants of one variety together for the better observance of these traits in their character.

Varieties 3 feet high—L'Adorable, Val d'Andorre, Fleur Parfait, Dolores, Mr. Cullingford, Miss Margaret. *Varieties 4 feet high*—Golden Eagle, Golden John Salter, Hero of Stoke Newington, Lady Hardinge, Lady Slade, Le Grand, Princess Teak, Princess Beatrice, Barbara, Fleur de Marie, Georges Saut, Yellow Perfection, Emperor of China, Chevalier Damage, Triomphe du Nord, Albert, Simon Delaux, Sœur Dorothee Souille, Golden Dragon, M. Henri Jacotot, Criterion, Meg Merrilies, Grandiflorum, Bronze Dragon, M. Desbrieux, M. Mousillac, Madame de Sevin, Duchess of Edinburgh, Madame Deville, Cullingfordi, Madame Godeaux, Princess Louise, Prince of Anemones, Angelina, Lady Talfourd, Miss Hope, Beauté des Jardins, Garnet, Père Delaux, Gloriosum, Martha Harding. *Varieties 5 feet high*—Hiver Fleuri, Grand d'Alveole, Nouvelle Alveole, Souvenir de l'Ardene, Flamme de Puncch, Dr. Macary, M. Astorg, Margot, Fabian de Medina, Marguerite Villageoise, Mlle. Lacroix, Cloth of Gold, Christine, Christine (pink), Dr. Sharpe, Distinction, Felicity, Golden Christine, Mrs. Forsyth, Mrs. Pethers, Gluck, Empress, King of Anemones, Baron Beust, White Globe, Empress Eugénie, General Bainbrigge, Guernsey Nugget, Jeanne d'Arc, Mrs. J. Crossfield, Mrs. Brumlees, Mrs. Dixon, Mrs. W. Shipman, Nil Desperandum, Pink Perfection, Refulgence, Mlle. Cabrol, Fernand Feral, Boule d'Or, Mrs. Sharpe, Mrs. Halliburton, Prince of Wales, St. Patrick, Progne, Madame Boucharlat, Rosa Bonheur, Ethel, Agréments de la Nature, Magnana Bonum, l'Incomparable, La Nymphe, l'Africaine. *Varieties 6 feet high*—Golden Empress, Queen of England, Empress of India, Alfred Salter, Lord Alcester, Jardin des Plantes, John Salter, Lord Derby, Mabel Ward, Mrs. George Glenny, Mrs. George Randle, Novelty, Cherub, Eve, Emily Dale, Beauty, Bronze Jardin des Plantes, Lady Carey, Venus, White Venus, Bronze Queen of England, Mlle. Madeleine Tezier, King of Crimsons, Madame Clos, Acquisition, Mdlne. Thérèse Clos, Triomphe de la Rue des Châlets, Elaine, Fanny Boucharlat, Jeanne Delaux, James Salter, Lady Selborne, Marguerite Marroch, Striatum Perfectum, Ceres, Duchess of Albany, Dormillon, Mrs. Mahood, Album Plenum, Bouquet Fait, William Robinson, Oracle, The Sultan, Cry Kang, Mlle. Moulise, M. Delaux, Mdlne. Laing, Alpha, Gorgeous. *Varieties 7 feet high*—Sarmia, Soleil Levant, Peter the Great, Mons. Ardene, Japonaise, Daimon, M. Brunet, M. Tarin, Balmorcan, Comtesse de Beauregard, Comte de Gerniny, Baron de Prailly, Red Gauntlet, Mrs. J. Wright, Mrs. Burbridge, Pelicun, Maiden's Blush, Beverley, Golden Beverley, Lord Wolsley, Prince Alfred, Prince of Wales, Mrs. Heath, Mr. Bunn, Fidibus, Lady Margaret. *Varieties 8 feet high*—Belle Paule, Fair Maid of Guernsey, Le Sceptre Toulousain, Thunberg, Madame Bertie Reublatler, Sir Stafford Carey. *Variety 10 feet high*—Mdlne. C. Audiguier.

CUTTING DOWN CHRYSANTHEMUMS.

JUDGING from the numerous examples of Chrysanthemum culture to be seen in private establishments, I am of opinion that the best methods of growing these autumn flowers are not so well known as they might be. The superiority of a well-grown collection on the restrictive system compared with a collection grown in the usual way is so great, that the points of difference and the method of proceeding are worth pointing out, especially as the present time is suitable for carrying out the cutting-down system. Some difference of opinion exists as to the merits of cutting down, but it is emphatically an exhibitor's question, and need not concern private growers. If the very finest blooms are desirable, *i.e.*, one bloom to a plant, cutting down is neither necessary nor desirable; but if quantity and not quality is wished for, then probably no better way exists than the usual pinching out of the points. On the other hand, if compact and comparatively dwarf plants with good healthy foliage down to the rims of the pots, and first-rate blooms are a desideratum, then the best way to attain this is by cutting the plants down. Assuming that the plants are healthy and in 6-inch pots and have not been pinched, they should be cut well into the hard wood. The exact whereabouts may easily be ascertained by a consideration of the number of shoots desirable. Generally speaking, unless for specimens, three to six shoots are enough; in that case three to six breaks should be allowed for. There need be no anxiety as to the pushing forth of the apparently dormant buds, as a few gentle syringings and a little less water at the roots will quickly set any doubts at rest on this head. As soon as they have broken well and have grown 2 inches or 3 inches, they should be potted in their flowering pots.

As soon as the new growth is long enough the plants should be staked, allowing a stick to every shoot. Bamboo canes, which may be had in 4-foot and 5-foot lengths, make excellent Chrysanthemum sticks, and they have the advantage of being rigid and durable, and also reasonable in price. Having decided on the number of shoots, all lateral growth should be pinched out immediately it can be got at, unless more than one bloom to a shoot is desired; in that case two, three, or more can be left of those lateral shoots near the top, but the blooms will not be so fine nor the effect nearly so striking as when each shoot carries one bloom only. Considerable discrimination is necessary at disbudding time in selecting the best buds to remain. Select the most central and finest buds, taking out the remainder as soon as they appear with a small sharp knife or Grape-thinning scissors. If the plants have never been neglected as regards water, have had copious supplies of weak liquid manure, been well syringed in hot, dry weather, greenfly and mildew kept at bay with sulphur and tobacco powder, and have stood during the summer in an open position fully exposed to the sun, a grand display of blooms will reward the cultivator, and well repay the attention and labour bestowed upon the plants. Some naturally tall growers (and amongst them are some of the best, such, for instance, as Madame Audignier, Comte de Gerniny, Fair Maid of Guernsey, &c.) refuse to grow dwarf, as, in spite of cutting down, they will average 6 feet to 7 feet. Such splendid varieties should not be discarded on that account, as they add much to the beauty of a collection or a group. F. W. SEERS.

Hova imperialis.—This is now in bloom at Guernsey House. It bears large waxy flowers of a reddish brown colour. It is one of the most handsome of the Hoyas, and is not often seen in bloom.

What are greenhouse flowers?—Will you kindly tell me through THE GARDEN if Azalea mollis and Roses are considered greenhouse plants, and eligible for a class of twelve cut stove and greenhouse flowers? At the Reading show held on June 2 the first prize was awarded to a box of cut flowers containing blooms of these plants. The judges when appealed to answered that Azalea mollis and Roses were greenhouse flowers.—ALFRED CLARK.

* * * We cannot imagine by what rule the plants you name can be classed as greenhouse plants in England, any more than such things as Likes, Lilies of the Valley, Spireas, Guelder Rose, Dillytras, or the many other hardy plants that are used by gardeners for early forcing, and therefore those you name are not eligible in a competition in which stove and greenhouse flowers only are asked for.—ED.

FLOWER GARDEN.

NARCISSUS HORSFIELDI.

SEEN in a strong clump, like that figured in the annexed woodcut, this Daffodil has, in my opinion, but one rival, and that a flower scarcely distinguishable from it except by a Daffodil expert—I mean Empress. Its noble flowers are well set off by the broad, glaucous foliage, which stands up stoutly, and contrasts in a marked way with the poor, green leafage of so many other kinds. The clump figured, the kind gift, some two or three years ago, of my good friend "Veronica," bore in a space of less than a square foot sixteen perfect blossoms, all of unusual size, the average being over 4 inches across. I find this Daffodil likes a cool, moist soil and partial shade, as it increases rapidly and flowers well under these conditions, in which maximus will barely exist. Amongst its neighbours which flourish best are Primula

Narcissus Horsfieldi. Engraved for THE GARDEN from a photograph sent by Mr. Greenwood Pim.

japonica, P. denticulata, P. rosea, P. sikkiensis, and Trillium grandiflorum. G. P.

Wulfenia carinthiaca.—How often one gets a wrong impression of a plant from having grown it badly! My opinion of this, after growing it for some years in a moderately dry part of a rock garden, was that it was worthless as a garden plant. It was given one chance more, a stock of young plants having been raised from seed and planted in a cool, damp place partially shaded. The fine, healthy, well-shaped leaves and well-coloured, purple, one-sided flowers, as enclosed (flowers a little past their best), show how very wrong was the first treatment and estimation of a good plant.—G. J.

Tulips for the border.—Although not commonly seen, except in botanic gardens, the species of Tulip have strong claims on those who delight in a rich display of colour in the border during the spring months. The various species offer a wide range of colouring, a few of the brightest hues, as *T. Gesneriana*, the parent of the florist's Tulip, and the grand Turkestan species known as *T. Greigi*, which has in addition bold foliage blotched with deep chocolate-purple. We noticed them recently in a bulb border at Kew, and were agreeably struck by their portly bearing and fitness for such positions. The two mentioned above are amongst the showiest, but a good selection would also comprise the quaint

T. cornuta, segments narrow and of a yellowish red; *T. elegans* (appropriately named), colour deep crimson; *T. Oculus solis*, also well named, the flowers being of a bright red; *T. sylvestris*, our common yellow species; *T. viridiflora*, which is a well-formed flower, the segments creamy yellow with wide greenish band down the centre; and *T. flava*, also of bold character, the flower of a soft yellow and immense size.—E.

PRIMROSES.

THE plan I have adopted of growing these may possibly meet "R. G.'s" (p. 485) requirements. It is one, moreover, that I can confidently recommend as giving the best results where the soil is not naturally favourable to this class of hardy flowers. I sow thinly in shallow boxes as soon as the seed is ripe, as then I can rely on nearly every seed germinating, and encourage continuous growth all through the following summer. Although I have spoken of sowing as soon as the seeds are ripe, I prefer to wait until the middle of August, which amounts to the same thing, as in that short time the germinating powers have not sensibly decreased. My reason for not sowing till that time is that the plants do not

One advantage gained by annually raising Primroses from seed and treating them as above described is a much earlier display of bloom. The continuous unchecked growth at the natural resting period of the Primrose induces an abnormally early flower development. It is just what happens in the case of the Persian Cyclamen, which, naturally a spring bloomer, is made, by a certain system of culture, to commence flowering at the close of the autumn. My plants began to bloom in October, and had the winter been mild, I should have gathered Primroses plentifully during the three dullest months of the year. The difference between them and older plants in this respect was most marked. Another winter I intend putting some of the plants in a cold frame, for I am sure that, with proper treatment in summer and shelter from cold and wet in winter, we may have good Primroses through the winter months. The quality of the blooms from one-year-old plants is so much higher than is obtained from older stools, that if this were the only gain, it would be worth the trouble of annually raising plants from seeds. Last year all my Polyanthuses were one-year-old plants, and the flowers were quite one-third larger than they are this season. J. C. B.

NARCISSUS TRIANDRUS.

I AM surprised to learn in THE GARDEN (p. 533) that Mr. Baker has identified Mr. Brockbank's lobed or campanulate form of this Narcissus as the *N. reflexus* of Brotero. It can scarcely be considered as a new or distinct variety, having been for some time familiar to all who have grown or observed *N. triandrus* in any considerable quantity. It seems that wherever the pale-coloured triandrus abounds, it varies largely, not only in the relative lengths of corona and perianth, but also in the form of the edge of the corona, of which all intermediate shapes may be picked out from a plain, straight edge to a boldly lobed form. As to the name, I believe it has been agreed by the Narcissus Committee, that for the present at least, the names calathinus and reflexus shall be dropped, and triandrus only used. Personally, I should prefer the adoption of the term reflexus, since triandrus is, as Mr. Brockbank mentions, a misnomer; while confusion might arise from the name calathinus having been applied also to *N. odoratus*. I do not understand what Mr. Brockbank means by saying it is clear that his specimen with the large corona belongs to *N. calathinus*. The relative size of corona is no differentiating character. Wherever the plant is found it is extremely variable in this respect, and I take it that a pinch of seed from any one bulb would give a variety of forms. In short, triandrus, reflexus, calathinus, are simply names of one and the same plant, though the illustrations attached to the names happened to be—indeed, could scarcely help being—made from three different forms of the flower. A botanist drawing the plant in the Isles de Glénan would be sure to find and represent something a little different to that which a botanist would gather and draw in Portugal or Spain, though the plants are entirely the same. The pretty name Ave Maria is probably given not only to the campanulate form, but to the pale triandrus generally. White flowers of a delicate appearance have often, in the south of Europe, the name of the Virgin Mary assigned to them. We are familiar with Madonna Lilies, and I have heard the Italian peasants call the little mountain *N. poeticus* Madonette, or little Madonnas. A friend of mine travelling in Spain some years ago told me he had seen a very pretty little white flower (he was no botanist) which the country folk called Ave Maria. This, I think, was in Aragon. G. H. ENGLEHEART.

A fairy Catchfly (*Silene pusilla*).—A very beautiful little white alpine plant. The plant no bigger than a little Moss, the flowers thick as stars in the milky way; white, star-like, exquisite in form, and, like so many alpine flowers, quite covering the vegetation. It is too small and fragile to be shown in a drawing. From Mr. James Backhouse, at York, to whom we are indebted for so many

pretty things in this way. Mr. Potter says it is easily grown and very hardy.—W. R.

NOTES ON HARDY FLOWERS.

THE warm weather of the last few days has had a magical effect upon vegetation, and our gardens are now wearing a summer look. Pæonies, Pyrethrums, and many other favourites are now fast opening their flowers. There are, at the present time, many plants of interest in bloom at Mr. T. S. Ware's nursery at Tottenham, a few of which we may note with advantage. Irises are few in number, but a form of the Rush Iris (*I. juncea*) merits attention; the flowers are of bold character and of a pleasing canary yellow. The dwarf Flag (*Iris pumila*) is one of the most interesting in bloom now; this produces its beautiful deep purplish violet flowers close to the ground, and in this respect it stands alone. A noteworthy species is *Iris longipetala*, with large flowers coloured with lilac on a white ground; a variety called *compacta* is well named; it has broader foliage, and the growth is more compact and dwarf, and is altogether very distinct. The scarlet Alum Root (*Heuchera sanguinea*) is effective just now, the flowers being of a bright red and freely produced; it is a good rockery plant; so also is the Golden Drop (*Onosma tauricum*), which bears in clusters yellow drooping flowers; this plant will thrive on a gravel heap, and there is a tuft at Tottenham flourishing to perfection in soil of this character, and with full exposure to the sun. Among the Anemones, the Snowdrop Windflower (*A. sylvestris*) is in bloom. Of this the Austrian form is much better than the English, the flowers pure white, with purple blotches at the base of the petals. *Primula japonica* is very showy on the rockery, with its bright whorls of crimson flowers. In moist spots the leaf growth is remarkably robust. *P. sikkimensis* is distinct, its large umbels of drooping yellow flowers, produced on stems about 18 inches high, having a graceful and delicate appearance. The orange-scarlet Iceland Poppy was also in fine condition; this is remarkably bright, and presents a contrast to the white and pale yellow forms. Lady's Slippers were very interesting. *Cypripedium Calceolus* was very fine, thriving freely in a moist, shady nook, screened from bright sun. *C. parviflorum*, a form of *C. pubescens*, the labellum yellow, and the sepals and petals brownish, with flowers sweetly scented and smaller than those of *pubescens*, but of a darker colour, is also worthy of note. *C. macranthum* is a gem, the flowers very large, and of a deep rosy crimson. We noticed a specimen in a shady, moist position, thriving freely in loam and limestone; it is one of the most lovely of all the hardy Lady's Slippers. The time of Lilies is not yet, but the earliest of all, *Lilium pyrenaicum* minor, is at its best. This is always the first to bloom; the flowers are pale yellow, with two divisions arching backwards. The major variety is later and not so free-flowering. *L. dahuricum*, a very dark form of *umbellatum*, we noticed in a pit; the flowers are rather small. *Lilium kantschatcense*, sometimes classed with the Fritillarias, is becoming scarce; it has small, almost black flowers, and is very dwarf. Tom Thumb Lily (*L. tenuifolium*) is also of small stature, but it has the glorious colour of the scarlet Martagon Lily, and is also sweetly scented. *Habelia rodopensis* is very rare, and will do for the choice rockery, but its pale lilac flowers lack brightness and beauty. The lovely spring Gentian was in full bloom; in colour this and the blue Gromwell (*Lithospermum prostratum*) are almost identical, both being of a remarkable depth of blue. *L. graminifolium* is a good rock plant, the colour a deep bluish purple. *Cyclobothra pulchella*, one of the hardiest of the group, produces at this season its fine yellow flowers, which give life to the garden. The flowers of St. Bruno's Lily (*Anthericum liliastrum*) are very conspicuous at the present time; the major variety is most vigorous and later than the type. This will be found one of the best plants for cutting. A bed of *Dodecatheon splendidum* was past its best, but there was enough left to show what a glorious plant this is for shady places; it fully deserves its name.

Ixiolirion tataricum, flowers bluish purple, reminds one of *Triteleia laxa*; it is of free growth, stands any amount of frost, and is proof against both dry and wet weather, though from its appearance we should not think this the case. *Camassias* are useful at this season, and there are several kinds. *C. Fraseri* is finer than the old Quamash (*C. esculenta*); it has flowers a trifle paler in colour, but they are larger. Mr. Ware has also a new form of elegant character, the flowers small, of a delicate lilac, and borne thickly in rather long spikes. *C. esculenta atro-carulea* is a good variety, the flowers conspicuous and of a deep purple. *Geum minimum* also deserves notice. This is a variety with reddish scarlet flowers, and it blooms throughout the winter if the weather is mild. It is a useful border plant. *Eremurus robustus* was showing a magnificent symmetrical spike; this, when fully developed, will give the plant an imposing appearance. The flowers are a delicate rose colour. It starts into growth very early, so that, unless when planted amongst shrubs or in some way protected, it is apt to be injured by spring frosts. E. C.

INDIAN PRIMULAS.

REFERRING to the remarks on these in THE GARDEN (p. 535) by Mr. W. Brockbank. I sowed in the spring of 1886 twenty packets of Indian *Primula* seeds, many of them supposed to be new. We raised plants from all the packets except Elwesi, supposed to be the finest of all *Primulas*. The first new kind to flower with us was *P. obtusifolia* var. *Gammicæna*. It received first-class certificates from the Royal Botanic and Royal Horticultural Societies about the end of March. Ten days later *P. Reidi* flowered, a lovely species with creamy white flowers, and having a distinct and exquisite perfume. Later, *P. geraniifolia* produced pretty trusses of rose-coloured flowers. This is also a very distinct species. The latest to flower are plants raised from a packet marked "*P. elongata*, yellow, near Choombie, about 11,000 feet near streams in shade, wet banks." This has proved itself to be *P. imperialis*, a synonym for *P. prolifera*. It may be best described as a yellow *P. japonica*; the flowers are rich deep yellow, and produced in whorls of eight or less on stems about 2 feet high. We have four plants of it now in full beauty.

We had two different packets of *P. reticulata*, but all the plants produced from them are *P. sikkimensis*. The varieties vary considerably in the colour and form of the flowers as well as the number on the trusses. If Mr. Brockbank took his plants to be *sikkimensis*, why make a species of a plant so much like another?

We had *P. capitata* (Hook.) and *P. bellidifolia* (King) in mixed packets, and raised two forms of *capitata*; nothing else; one, a major form, which Mr. Wilson exhibited in the autumn at South Kensington last year. Ours flowered a week later. It received a certificate as a new form. We have raised a distinct species from packets of *P. Kingi*, although most of the plants were *sikkimensis*; they have not yet flowered, that is, those that were not *sikkimensis*.

We also sowed seeds of *P. soldanelloides*, but got no plants; this must be linked with Elwesi as a failure. It is but right to add that Mr. Dewar saw our plants of the supposed *reticulata*, and pronounced them to be *sikkimensis*. Messrs. Veitch, of Chelsea, had a similar experience.

J. DOUGLAS.

Aucubas.—Although "T," in THE GARDEN of 28th of May (p. 482), says that a spot not too much exposed to the sun should be chosen for seedlings, I think it necessary to inform your readers that my experience has taught me that the *Aucuba* requires a complete shade, and that they grow best under other trees in the north of the garden; and this makes them more useful, because they thus hide naked trunks. They are very fine during the whole winter, as they do not lose their leaves, and are covered with their pretty red berries. But to obtain this it is necessary to intermix the males and females. The *Aucubas*, and particularly the dwarf

varieties, are also very handsome as pot plants for indoor decoration, and the American florists grow them largely for that purpose. As the males and females are different in foliage, it is advisable to sow all the seeds, because the offspring will be different from the parents, and some fine new spotted varieties can thus be obtained. Of course, the females are preferable for pot culture on account of their berries.—JEAN SISLEY, *Monplaisir, Lyons*.

VIOLETS.

IT is exceedingly interesting to find so excellent a gardener as "J. C. B." is advocating the raising of single Violets from seed. But having lived many years in a district where single Violets, and specially the Russian, Superb, and The Czar, are grown in vast quantities, and having grown both these and *Victoria Regina* largely also, I have never yet met with natural seedlings, or, at least, only in very small numbers. Still further, I have not heard the market growers complain of their stocks being affected by seedlings. One would think that were Violets naturally productive of fertile seed, when plants were grown in vast quantities on the same ground for at least three years successively, seedlings would be abundant, and yet I have not seen any. On the whole, the market growers would, I think, prefer to stick to the present plan of renewing their plants, which is invariably done as soon as possible after the last bloom is gathered. As I have said, the plants remain in the same spot about three years, and at the end of that period have become big clumps. When replanting is decided on, the outer margins of these clumps are cut off with a spade, shaken out, pulled to pieces, and portions formed into young plants, which are dibbled perhaps out in the open in rows at 2 feet apart, or else in the orchards beneath the standard trees—the favourite place—at such intervals as may be most convenient. Violets endure drought pretty well, for I have seen breadths after replanting to be almost withered and leafless, and yet a month later green and full of vigour. By the autumn these have become big tufts, and early in the following spring produce fine flowers in plenty. The young plants or pieces are simply dibbled in, perhaps a bit roughly, but the result is as good as if half a dozen chapters of directions had been written and implicitly followed. I have but recently seen a similar process followed in the case of double Violets, but planted on a broad, sloping, west border beneath a high Hawthorn hedge. The soil is of the ordinary field kind, but well manured, and the grower turns out thousands of fine plants every autumn with extreme ease. He has, of whites, *Comte de Brazza* and *fragrantissima*, both excellent; *Marie Louise* and *Neapolitan*, mauve; and the fine old *King of Doubles*. It only needs Mr. Chambers' fine new double blue kind to be added to these to make the best possible half dozen of double Violets. London fogs are the chief enemies of Violets in this locality, but more especially the double varieties. Harm does not arise because the plants lack robustness or have not been well seasoned, but the fog is a distressing metropolitan adjunct to which Violets are victims. Even in frames they are not always safe; still in such case the injury done is materially alleviated. After all, to our many growers Violets remain one of the most profitable of market flowers. A. D.

Golden Meadow-sweet.—The golden-leaved form of our common *Spiræa Ulmaria* is remarkably bright, showing up conspicuously in the rock garden at Kew. This and the golden *Moneywort* rank amongst the best of our variegated hardy plants.—E.

A combination.—An exceedingly beautiful combination is made by clumps of *S. domon's Seal* and *Dielytra spectabilis* intermixed. The best position is one somewhat protected from late frosts, as the latter is tender to some extent, but still when grown thus naturally it blooms during May and June, and produces richer coloured flowers than when under glass. Both the above plants have a pendulous habit of growth, and produce a very charming effect when strong and well established.—D.

Aquilegias.—The Columbine is naturally the most striking and effective of garden flowers, but some of the garden varieties of *coronaria* are lumpy and associated with dull leaden colours. Still, the

flowers of the best kinds, such as glandulosa, chrysantha, cærulea, and californica, are very elegant and beautiful, although none have more beauty allied to size than the first named. But that is a dwarf and somewhat weak grower, lacking that robust habit found in the strong chrysantha, for instance, which once well established seems imperishable. But it is a curious fact, so far as my experience has gone, that intercrossing these two kinds seems to induce even more robust growth than chrysantha exhibits. That is hardly the result looked for in crossing a weak with a strong kind, but the strong chrysantha, being the pollen parent, seems to have so strongly impressed itself upon the weaker, that the seedlings are much more robust in growth than those of chrysantha itself. A cross made a few years since between chrysantha and a white form of coronaria gave a batch nearly all rosy coloured and a few flowers spurless, but the growth is, as compared with others, remarkable, the line of plants coming up year after year with wonderful vigour. It may be that in intercrossing species or forms of species we spoil the floral characters of these species, but if we get robust and enduring habit, very much is gained, whilst I have not yet seen the product of such cross which is not pleasing as a garden flower, and many of Mr. Douglas's hybrids, for example, are very beautiful. Glandulosa from seed sown in a frame last spring is now giving plants carrying ten to twelve blooms, which, transferred to pots, are lovely objects in the greenhouse.—A. D.

Spring bedding.—When at Plawhatch a few days ago I could not help admiring the spring bedding, which was at its best. The place is situated on very high ground, and is consequently exposed. After the long winter one would scarcely have expected to see things looking so well. Mr. Draper, the gardener, informed me that he always plants much closer than is usual for spring bedding, as experience has taught him that the plants stand severe weather much better. When the surface of the beds is perfectly covered, each plant protects its neighbour, and it is obvious the frost cannot have the same hold upon them as when there are open spaces between each plant. As mentioned previously, the beds are now at their best, and this fact raises the question whether spring bedding is not a mistake. Although the plants have survived the cold and look well, it is only the recent warmth that has brought them to their present state of perfection, and now the beds are wanted for the summer display. No one would think of disturbing the plants when in full beauty; therefore the summer bedders will be fully a month before they are in position. Bearing in mind that the spring bedders are short-lived, this loss of time becomes a serious matter. On the other hand, who could tolerate bare beds close to the house from October to June? Slowly, but surely, the love for beautiful hardy flowers is increasing, and at the same time the bedding craze is becoming a thing of the past. As an example of this, a nurseryman, who used to sell great quantities of bedding plants, tells me that there is not nearly the demand there used to be, and several large plant houses formerly devoted to them are now utilised for growing cut flowers for market.—A. HERRINGTON.

A new Jacob's Ladder.—I should be glad of your opinion of this. As it grows with us, it is a thoroughly good garden plant, far better than any other of its family, and a long way ahead of Polemonium Richardsoni. It is a handsome and graceful plant, 2 feet high, foliage very good and symmetrical, and of a fresh, pale green colour; the flowers, the pretty grey-blue that you see, with bright yellow anthers, measure on an average $1\frac{1}{2}$ inches across, often $1\frac{3}{4}$ inches, and are carried in compact, branched heads of twenty or thereabouts. It was raised here in 1884, from seed sent from the Saharanpur garden. The packet was labelled "without name;" it was probably collected wild, as other packets accompanying it were marked with the elevation. Botanically it is not distinct from *P. cæruleum*, so reported from Kew, where the first flowers were sent for identification. I therefore know it as a fine Himalayan Jacob's Ladder, and

have given it to one or two friends under that name. It is perfectly hardy, and will grow, as far as I know, in any part of any garden, only avoiding over-rich treatment, when, especially in a damp climate, it is shy to flower. Here it is perfectly free, and certainly a good thing.—G. JEKYLL, *Munstead, Godalming.*

* * A very graceful Jacob's Ladder, sent by Mr. Duthie, Saharanpur, who will, no doubt, kindly supply a name for it.—ED.

WORK AMONGST JUNE FLOWERS.

THE latest of the Auriculas are now quite over. Even the latest alpinæ in a shady position in the rock garden could not stand the heavy rains of the last forty-eight hours. The fancier must not be idle; he will have plenty to do in keeping his plants quite free from insect pests. As soon as warm weather sets in, it is difficult to say whether the green-fly on the leaves or the white Auricula aphid on the roots increase most rapidly. For the destruction of green-fly fumigating with Tobacco smoke is the most speedy and the most certain remedy. The woolly aphid on the roots can only be effectually dealt with by turning the plants out of the pots and carefully removing the pest, either by washing the roots if they are very badly attacked, or, if only slightly infested, by removing the aphid with the fingers. Repot the plants in clean pots, and use sweet turfy loam, enriched with a fourth part of decayed stable manure, also leaf-mould and sand. The small seedlings and the offsets removed from the parent plants in the spring must also be repotted when necessary. On the careful attention which the plants receive at this season their future well-being depends. Full cultural instructions have been given in previous numbers of THE GARDEN; it is enough now to remind growers of the importance of attending to the work in good time.

THE TULIPS are now in full beauty. Last year, on the 26th of May, they were in about the same stage as they are now. It is now, as I write, the 4th of June, a difference of only nine days; but a few warm nights—the temperature ranging sometimes above 50° as a minimum—has brought them on as if by magic. They were planted on the Dahlia ground, and that having been very richly manured, the flowers are much larger and brighter in colour than usual. Some of the very finest are the following: Bizarres—Sir J. Paxton, very dark, heavy flame on clear yellow ground; Everard, scarlet flame; Colbert, deep rich gold, maroon flame; Dr. Hardy, a more refined flower than Everard; Masterpiece, the best-feathered bizarre and the earliest; George Hayward, grand variety. In byblømens, Lord Denman, a large, handsome variety, was the earliest; Friar Tuck, a handsome feathered form; Duchess of Sutherland, very fine and the darkest byblømen, except Mrs. Jackson, which is a very striking variety, but the stamens are stained; David Jackson has never gone out of the breeder form with us. Talisman must be put down as the finest flamed byblømen; the flowers are so correctly marked and of the largest size.

In roses, Chamer is pre-eminently a flamed flower; it is not only of the largest size, but rich in colour; Heroine, very fine; Mabel, large and fine, broken from the breeder state this year; Lady Sefton, flamed scarlet; Madame St. Arnaud, very delicately flamed clear rose; Pretty Jane, large and fine, broken this year from the breeder form; Lady Catherine Gordon, flamed scarlet; Tomlin's Fanny, distinct and pretty. These are a few of the most striking at present in flower.

PINKS showed signs of suffering early in the year, but we gave a good surface dressing of rich compost, and they have started into vigorous growth and promise to give a large quantity of bloom; they generally come into flower about a month later than the Tulips. Ranunculuses are also growing with remarkable vigour, and show the strongest bloom that it was ever my good fortune to see, and not a plant has missed. The ground was rather dry a few days ago, and I contemplated giving them a liberal watering, but a good shower of warm rain

came on the 2nd and again on the 3rd, with a night temperature of 51° as the lowest point, and the leaves have become brittle with the rich supply of moisture. May, June, and July are all pleasant months for the florist, who grows full collections of these fine old favourite flowers. The double Anemones are just opening their many coloured flowers; they are not a week behind the Tulips, and before these two are well over the Pinks and Ranunculuses will be in bloom. The forcing Pink pipings ought to have been put in by the end of April, and by this time ready to be planted out in the open ground; they will, if well treated, form large clumps by the end of September; at that time they may be potted up to become established before winter sets in. In less than a month the pipings of the laced varieties should also be taken off and planted in boxes, where they soon produce roots in a frame partially shaded. The successful culture of these depends upon the attention the young plants receive after they are rooted. It is necessary that they should be grown into good strong plants by the end of September at the latest. They ought to be planted by the first days of October into the beds where they are to flower.

CARNATIONS AND PICOTEES in pots are receiving a considerable share of attention; they also show the effects of the warm nights and genial rains. We are now staking them, and have also placed about half an inch of rich compost on the surface of the pots. All that they require now is to see that they receive enough water at the roots when the weather is dry. In hot, dry weather they are often attacked by green-fly, which can be destroyed by dusting with tobacco powder. Maggots lurk in the axils of the leaves, and at night they issue forth to eat the tender buds. Thrips are more troublesome than either, but they can be kept off by syringing the plants daily in dry weather. The seedlings from seeds sown in April are now sturdy young plants; they are in boxes 2 inches or 3 inches apart, but in a few weeks they may be planted out in a bed in the garden, and by the end of the season will make vigorous established plants, which will defy the severest winters. Tree or perpetual-flowering Carnations are best out of doors now; the pots may be neatly arranged on a border of ashes, from which the water can run away freely. However much the plants may be cared for under glass, they never make the same healthy, stocky specimens as those produced in an open position out of doors. The plants must not be allowed to become root-bound before they are repotted into their flowering pots. The weather being so fine on the 3rd, we took advantage of it to plant out the Dahlias. It was a question whether to plant out at once, or to repot them into larger pots, but being pressed with work at this season and the weather being so favourable, labour was saved by planting them out at once. The less risky way would have been to repot them, place in a cold frame, and plant out the stronger plants in two or three weeks. If there is danger of frost during the next ten days, it is easy to invert a pot over each plant at night, removing it in the morning.

PANSIES are flowering profusely from plants raised from cuttings in August last. The young plants were kept in boxes during the winter, and were planted out early in April. We grow the largest proportion of what are termed fancyes; these have very richly coloured flowers, but we cannot omit a liberal proportion of the selfs, the white and yellow ground varieties. By and by the flowers will show a tendency to degenerate, but they are renewed by picking all the flowers off, surfacing the beds with rich manure, and pegging down the growths into it. The roots soon lay hold of the rich stimulant, and a second splendid display of flowers is the result. J. DOUGLAS.

Primula reticulata—I think Mr. Brockbank will prove mistaken in believing that he has got *P. reticulata* in flower. I have several hundred seedlings raised from seed, which came from India labelled *P. reticulata*, but they are all *P. sikkimensis*. But if Mr. Brockbank has the true plant, I hope he will show it at some scientific meeting, as I believe

it has not yet been seen in cultivation. Several species sent to me from those who have raised plants from the same seed have all proved *P. sikkimensis*. *P. reticulata* has a leaf with a cordate base, a very distinct character in Himalayan Primroses. I believe I have it, but the plants are very small and came up very late last year from a packet marked "unknown." They will not flower till next spring, and I fear may die, as many Himalayan Primroses do in English gardens, in their second winter.—C. WOLLEY DOD, *Edge Hall*.

Ranunculus Lyalli.—This excellent plant, almost new in English gardens, is now in good flower at Mr. Bartholomew's, Park House, Reading. It is a giant Buttercup, of a dazzling white, 2½ inches across, flowering in branching heads, like a Marsh Marigold. The blooms have a double row of petals, which gives a half double look to the flowers. The root leaves are large and handsome, also like Marsh Marigold, but peltate. Anyone wishing to see this good new plant from the Antipodes has permission to call at Park House, where it will be in bloom for some ten days from the present date (June 19), as nearly as may be judged.—G. J.

Chrysanthemum multicaulis.—A plant to me new and which I am this year growing for the first time. It is from the Continent. A hardy annual of very dwarf Daisy-like growth, the foliage lying round close to the ground. The flowers, about 1½ inches over, are single, bright yellow, and thrown up singly, just as the flowers of the Daisy are on single stems. Curiously enough, also, the flowers close up at night. If a name may be coined, I venture to dub it the Butter Daisy, for it resembles *Bellis perennis* much more than it does the *Chrysanthemum* tribe. Not many flowers are yet open, but I anticipate when in full bloom it will prove to be a remarkably pretty thing, and a real gain to rock plants.—A. D.

Coloured Ivy leaves.—Mr. Groom, in his article on "Raids on Wild Flowers" in *THE GARDEN* (p. 510), alludes to the pretty colour which some of the Ivy leaves assume during the winter months, and "presumes it is owing to the nature of the soil." I cannot agree with him as to the cause, for if it was owing to the soil, why should we see these beautiful leaves all over the country? They are generally found in places fully exposed to the sunlight, and from this fact I have come to the conclusion that the colour is caused by the action of light upon the fluid contents of the leaves at a time when they are in a dormant state. What becomes of the colour in spring when growth commences? It disappears. Has Mr. Groom ever noticed that when *Pelargoniums* are put out to harden off previous to planting the leaves assume various colours, owing no doubt to their being starved in a pot and growth at a standstill? The colour disappears as soon as fresh growth commences.—A. HERRINGTON.

SHORT NOTES.—FLOWER.

Mossy Saxifrage (*Saxifraga hypnoides*).—This charming plant we saw growing well on a garden wall at Kew. It was in full flower, notwithstanding its dry and sunny position.—E.

Marica cœrulea.—A large lily of remarkable beauty, bearing on a tall and gracefully arching stem a succession of blue flowers about the size of *Iris Kämpferi* in twos and threes at a time. Now in bloom at Park House, Reading.—G. J.

Alpine Wallflower (*Cheiranthus alpinus*).—This brightens the rock garden at Chiswick at the present time, and several plants were blooming in one of the pits. It is of dwarf habit, and the showy yellow flowers are borne with great freedom.—E.

Iris susiana.—I have a plant of *Iris susiana* bearing a strong flower spike, a flower of which will be open in a few days. The plant has stood planted under a wall facing south all through the past severe winter in a small back garden, and has had no protection other than that of the wall.—JAMES RONCA.

Herbaceous Pæonies.—Will any of your readers give me the names of a few double varieties that will thrive in the neighbourhood of London (Clapham)? I have planted several this spring, but they all seem to be dying off, although I have taken great care in mulching and manuring them, &c.—RICHARD VESLEY.

Heering salad.—Mr. Barnandt, of Holland, says the name "heering sallats" is applied in Holland to carpet bedding. The heering salad was composed of herrings, the

yolks of eggs, mustard, and sundry vegetable materials, each differing in colour, arranged in patterns in dishes, and was set outside the restaurant to entice the customers in. Not a bad name!

The Plantain leaved Leopard's-bane (*Doronicum plantagineum excelsum*).—This is a fine plant for the enrichment of the border in spring. It may be regarded as a very robust form of the type; the flowers are yellow, and make a great show of colour.—C.

PHACELIA CAMPANULARIA.

ANNUALS, and especially those of showy character, ought to make features in every garden, however small it may be. They are of distinct habit and bright appearance, besides being highly useful in many ways for which plants of a perennial character are not adapted. In borders or beds of permanent bulbs, annuals such as the *Phacelia* are remarkably useful for giving colour to the garden during the most enjoyable months of the year. Bulbs, generally speaking, are at rest during the late summer and early autumn months, and this is the time when the garden should wear a gay aspect. This may be accomplished by a judicious use of these charming plants. Great care, of course, is required in selecting suitable kinds; for instance, where

Phacelia campanularia.

the ground is heavy and the bulbs require all the sun they can obtain to ripen properly, it would not do to plant those of dense growth; whereas in a light soil the selection as to habit is of no consequence. Many of them are so floriferous, that the display will abundantly compensate for the trouble of sowing and thinning, which in the case of hardy kinds, as *Phacelias*, is a small matter. When sown in the open ground—and we believe this practice to be far preferable to sowing in pots—the main thing will be to sow the seed thinly. As soon as the young seedlings have produced their first leaves, thin out to the required distance apart, say from 6 inches to 12 inches, as plenty of room is essential to the development of foliage and flowers. *P. campanularia* (here illustrated) is one of the latest introductions, the seeds having been received from California about five years ago. The flowers are smaller than those of the old *Phacelia Whitlavia* (*Whitlavia grandiflora*), but much brighter in colour, being vivid gentian-blue, and very striking when grown in a mass. It ripens seed freely in this country. *P. Parryi*, a species with deep violet flowers, is also well

worth growing; it makes a charming companion to the above. Others, such as *P. loasifolia*, *Menziesii*, &c., are also very desirable. K.

HERBACEOUS PLANTS AT MANCHESTER.

A GRAND collection of plants was brought together at Manchester, the two most noticeable features being the classes for Orchids and herbaceous plants. In both of these departments Manchester stands unrivalled. There may be finer collections of Orchids in the south, and there is nothing in the north to equal those of Sir Trevor Lawrence and Baron Schroeder. There is, however, nothing in London or anywhere else to equal the grand exhibits of herbaceous plants contributed both by professional growers and amateurs. Nowhere are herbaceous plants so carefully and well exhibited as at Manchester; they are neither bunches of cut flowers, huddled together, nor plants dug up out of the ground, but are carefully grown in the pots in which they are exhibited, and do not therefore flag when the exhibition is half over. At Manchester both nurserymen and amateurs compete. One exhibit alone, that of Messrs. James Dickson and Sons, Chester, occupied 300 square feet; while Messrs. Arthur Dickson and Son had a large exhibit; and Messrs. Broome, Mellor, &c., amongst amateurs, contributed good collections.

Amongst hardy plants there were many common enough, but from the excellent manner in which they were exhibited, had all the charms of novelty. This was the case with some large pans of the Cobweb Houseleek (*Sempervivum arachnoideum*). The plants were shown in pans about 18 in. in diameter, on which pieces of stone had been placed, so as to form a slight elevation. Over these the Houseleek creeps irregularly, and forms a pleasing carpet. With exposure to wet these curious plants lose their peculiar characteristic. There were several good specimens of Lilies exhibited, amongst them the fine Bermuda Lily (*L. longiflorum* Harris). Besides these were good examples of the following early-flowering Lilies: Crimson-anthered Lily (*L. Szovitzianum*), one of the most beautiful of all; Nankeen Lily (*L. testaceum*), tall and stately, with its beautiful uniform colour; Siberian Orange Lily (*L. davuricum*); and the ordinary Madonna Lily (*L. candidum*), which as a white Lily is unsurpassed, and has proved itself amenable both to pot culture and forcing. Terrestrial Orchids were exhibited in great beauty. I have never seen our common native Lady's Slipper (*Cypripedium Calceolus*) in such fine condition. Then there was a beautiful group of the lovely Mocassin Flower (*Cypripedium spectabile*) in fine flower and foliage; the yellow Mocassin flower was also in fine condition; it is somewhat strange that the American species is more easy to cultivate than our native ones. I have found it so, and I believe others are of the same opinion.

Of what we term more especially alpine plants there were some beautiful pans; the spring Gentian (*Gentiana verna*) was one mass of bloom, and what can be more lovely than this when well grown? Alpine Pink (*Dianthus alpinus*) was superb, but there is some confusion about these Pinks that I should like some day to touch upon. It is a lovely little thing when smothered with its bright pink flowers almost on the ground itself. Charming little colonies of the Bird's-eye Primrose (*Primula farinosa*) were very lovely; also *P. Munroi*. *P. obconica* can hardly be looked upon as a hardy plant, but it was very attractive. *Armeria Lauchiana* was also a pretty plant with stems 4 inches to 6 inches in height; its rosy crimson flowers make it very bright, while its dense close habit fits it for edgings. The Androsaces—difficult plants to manage—were represented by probably the easiest grown of the family, *A. sarmentosa*, which rapidly covers the ground. There was an excellent example of it here smothered with flowers; the woolly-leaved *A. lanuginosa* was also exhibited. It was somewhat late for the Anemones, but the Snowdrop Anemone (*A. sylvestris*) was in good condition with its pure white flowers; but let growers be careful, as it is of very free growth, so that once it obtains a firm hold, it is almost impossible to eradicate it. The charming yellow Wood Anemone (*A. ranunculoides*), bright yellow in colour, was also

interesting. There were some good pots of the very fine Sir Watkin Daffodil, which still maintains its character. Plantain-leaved Leopard's-bane (*Doronicum plantagineum excelsum*) was shown, but this fine showy plant can only be seen to perfection when growing in a border where it can have plenty of room. *Tulipa retroflexa* attracted attention, as did also *T. cornuta*. Iceland Poppies were also well shown. The Quamash (*Camassia esculenta atro-violacea*) was very beautiful; it is an improvement on the ordinary type. The ramosus section of *Gladiolus* is excellent for early blooming in pots, and some of the varieties, as *Rosy Gem*, *ardens*, *elegantissimus*, and *Ne Plus Ultra*, were shown in fine condition, and are very useful for cutting. They are always exhibited well at Manchester. *Pæonia tenuifolia* and its double variety are pretty and interesting. *Phlox Nelsoni* and *setacea* were in good condition, and also a species named *Phlox stellaris*, which has a pretty drooping habit and bears numerous lilac-white flowers. Then there was the charming *Rock Forget-me-not* (*Omphalodes Lucilike*), and *Celsia Areturus* makes a fine pot of yellow bloom, and, although not so showy as the fine *Celsia cretica*, is still very pretty.

There was, of course, a good display of perennial Larkspurs, which are so effective in the garden. Of these, the lovely variety known as *Belladonna* was fine, but there were many good varieties and some excellent seedlings from Messrs. Jas. Dickson and Sons. These will soon be in perfection in the garden, and it was pleasant to have a view of them somewhat in advance. By gentle forcing, and in some instances retarding, the different varieties can be exhibited together, and thus lovers of these beautiful and interesting plants have an opportunity of selecting either for rockery or garden and avoiding those of indifferent character.

DELTA.

FRUIT GARDEN.

W. COLEMAN.

UNHEATED FRUIT HOUSES.

ALTHOUGH I am strongly in favour of a flow and return pipe, if not for forcing purposes, certainly for the protection of the flowers in the spring, for ripening the wood in the autumn, and making the structure useful and enjoyable through the winter, there are many ways in which unheated houses may be made useful and profitable. In gardens of note where forcing is carried on with spirit, a large cold house or glass-roofed shed is invaluable all through the spring for hardening off and retarding plants, and now, even the middle of June, I question if a structure of this kind, wherever situated, will not be found full, if not crowded. Plant growers can, of course, enumerate an immense number of plants, including forced *Roses*, *sub-tropicals*, &c., which require a certain amount of hardening before they are fit for turning out into the open air; also of plants coming on for summer decoration when the forced stock is over and hard-wooded specimens are making their growth. None of these cultivators would object to hot-water pipes, but, provided they were not forthcoming, few, if any, would decline the house without them.

To the fruit forceer they are equally valuable for precisely the same purposes, as orchard houses can be relieved by the transfer of pot trees that have failed or given crops of fruit, also of *Pears* and *Plums* that it is their wish to work through a cold house to the open air to ripen their fruit. Many of the better varieties of early and mid-season *Pears*, which can be had in better condition from the open air than from glasshouses, require gradually inuring to a free circulation of fresh air until settled summer weather favours the final move, and this structure I have found ex-

tremely well adapted to the purpose. For retarding or keeping ripe *Strawberries*, or ripening up late varieties, a few shelves near the glass not only do good service, but they also relieve the mind, as these breeders of parasites and insects can be quarantined as it were away from the occupants of the forcing houses. When cleared of these, no cold house need be allowed to stand idle, as *Tomatoes* got well advanced in another place will yield heavy crops of fruit throughout the latter part of the summer and the autumn. From this time through the early part of the winter the vegetable gardener, and possibly the *Chrysanthemum* grower, would have their pull, and although the latter might find stagnant moisture a drawback, the former could easily occupy the whole of the space with his *Veitch's Cauliflower* and *Protecting Broccoli*, his pot *Parsley* and *salading*. In the unheated orchard house failures sometimes occur, but fruit trees of all kinds, *Peaches* and *Nectarines* included, have been grown plentifully and good. Indeed, these fruits, also the better kinds of *Gages*, *Golden Drops*, and choice *Cherries*, grow to a large size and finish perfectly in ordinary seasons. In a large lean-to house here without the aid of fire-heat I grew some of my best autumn *Peaches* and *Nectarines* for many years, and I do not remember ever having missed a crop. When at last I succeeded in getting it heated, I at once set about putting up a span roof with rough boarded sides, and furnished it with a set of old pot and tub *Peaches*, which many gardeners would have thrown into the fire. These relieved of their pots and tubs and mounded round with soil soon made fresh, healthy wood, and as yet, this year included, they have set enormous crops of fruit. The *Peach* and *Nectarine*, however, although less hardy than the *Plum* or *Cherry*, when overtaken by intense frost on open walls, in cold houses, are not so liable to be affected by a damp atmosphere when in flower, and for this reason I consider them safer and better adapted to cold or unheated house culture. All sticklers for colour, myself included, consider *Peaches* from standard or bush trees less valuable than fruit from trellises; but a fair percentage can be coloured, and where *Peaches* are used in a multitude of ways, as we use them here, pale *Peaches* can be turned to profitable account. As all the numerous varieties are not alike suitable for this mode of culture, very late sorts, like *Walburton*, the *Mignonnes*, whose buds suffer from damp in winter, and others subject to mildew, should be avoided. *Bellegarde*, *Stirling Castle*, *Violette Hative*, *Alexandra*, *Noblesse*, *A Bee*, *Hale's Early*, *Crimson Galande*, *Belle de Doné*, and *Magdala* succeed well with me. *Prince of Wales*, *Barrington*, *Sea Eagle*, and the *Nectarine Peach* I have tried, but, owing to the great weight of their fruit, which turns them point downwards, and their lateness, they do not answer my purpose so well as the preceding. Of *Nectarines*, the latest, like *Victoria*, excluded, all the sorts I have tried answer very well. The old *Elsruhe*, *Stanwick Elruge*, *Violette Hative*, and *Lord Napier* are excellent—good croppers and hardy. In the south of England, where the climate is little inferior to that of Jersey, suitable varieties of *Grapes* are now grown without the aid of fire-heat; and, if I mistake not, Mr. Worthington Smith for years has grown good *Madresfield Court Muscats* near London. The price of good *Grapes* now does not leave a margin for unnecessary expense; therefore, those who have the command of warm sheltered spots should give the *Hamburgh*, *Madresfield*, *Royal Muscadine*, the best of the *Sweetwaters*, and *Foster's Seedling* a

trial. When in the neighbourhood of Gosport the other day, I learned that many amateurs had tried and succeeded with *Hamburghs*. What they can do near the sea, skilful gardeners may accomplish further inland. I conclude by saying heated houses are preferable to cold ones; but those who cannot get the first may derive much pleasure from the use of glass alone without the aid of fire-heat.

APPLE BLOSSOM.

IN view of the suggestions made in THE GARDEN, p. 507, that note should be taken of the varieties of Apples which make the most ornamental trees, a close observation of all the sorts which have flowered freely here (Berks) this year has been made, with several interesting results. In the first place, it would seem that just as the varieties producing the most highly flavoured fruit are usually the worst growers and most liable to canker, so the sorts whose fruit is particularly brilliant in colour have generally pale flowers, which are not conspicuously ornamental. A notable instance of this is *Cox's Pomona*, a variety with very bright and beautiful fruit, but of which the flower is almost white, even the buds being only of a sort of yellowish colour with a faint pinky tint. Now, *Apple blossom* which has not at least bright rose-tipped buds is hardly worthy of the name, and is certainly not worthy of inclusion in an earthly paradise where its presence is only desired, as on a flowering shrub or ornamental tree; so that a look-out has been kept for varieties which, while forming handsome trees, produce most freely and constantly the largest and brightest blossoms. It is consequently a mere accident that the list includes many of the very best—mostly cooking—Apples; but such is nevertheless the case. One of the best and brightest of all, making a good tree, free and constant, sheeted with bloom and glowing buds, and with a first-rate cooking *Apple*, is *Hawthornden*, commonly called *Old Hawthornden*; and next to it, perhaps, in freedom and brightness of flower, and rather before it in value of fruit, comes *Lane's Prince Albert*. *Lord Derby* is exceedingly handsome, producing great clusters of very large flowers and grand crimson buds, making a handsome tree and bearing first-rate fruit. The flowers of *Ringer* are very large and abundant, and the buds bright red, as are those of *Stirling Castle*, while both varieties are first-rate Apples and make good-looking trees. *Annie Elizabeth* and *Lord Suffield* produce magnificent and highly coloured blossoms, but in both there is rather a purplish tint underlying the red of the buds, which detracts somewhat from their brightness; the exceptionally handsome habit of the former, however, and the profusion and general value of the latter, involve their inclusion even in a select list. The flowers of *Dumelow's Seedling* are rather pale, but very good-looking, the buds being of a clear fleshy pink colour; they are very freely produced, and the fruit is perhaps the best all-round late cooking *Apple*. This variety has many synonyms, of which the most common is *Wellington*. *Court Pendu Plat* makes a handsome tree, and flowers so late that the brilliant red buds with which it is constantly furnished are always conspicuous among the paler cloud of expanded or passing blossom of other varieties with which it may be associated. *Hambledon Deux Ans* makes a large and striking tree, especially as a standard, producing freely its well formed flowers and fairly bright-coloured buds; and *Barchard's Seedling*, though less useful, makes an even gayer standard tree, either when in bloom or when covered with bright yellow, red-streaked fruit. *Golden Pippins* also make fine standards, and although the flowers are rather paler and not over large, yet they are produced in such masses as to be highly effective. *Warner's King* (syn., *D. T. Fish*) is good, well coloured, and constant, and the moderate-sized flowers of *Blenheim Orange* are pretty enough upon large trees, but not sufficiently freely produced upon young plants. *Tom Putt* is very handsome and good in all ways, in flower, fruit, and form of tree, and the same may be said of *Mère de Ménage*, in spite of its flowers being

rather pale. Lady Hemiker, a first-rate and showy Apple, has handsome, solid-looking flowers and bright pink buds, but does not always make a well-formed tree; and Sturmer Pippin, a very good-looking tree, has large flowers and bright red buds, which, however, lose their colour somewhat rapidly. Frogmore Prolific is not so red in bud as some varieties, but is nevertheless very good, and always flowers abundantly. Loddington Pippin and Bedfordshire Foundling both produce very beautiful round flowers in large clusters, rather pale in bud perhaps, but most attractive, and the latter especially a handsome tree. Catshead has one of the largest individual blossoms among Apples, but it is hardly free enough; Cellini, though only of moderate size and pale, is not so dingy looking as Cox's Pomona, and is so free and constant as to be effective, and the same may be said of King of the Pippins and Tewkesbury Baron.

Of the paler-coloured varieties one of the handsomest is Grand Sultan, with very large, almost pure white, flowers throughout, and another is Lord Grosvenor, with exceedingly handsome round flowers and fresh, though not deep-coloured buds. It is interesting to note that this variety, which some growers have asserted to be identical with Jolly Beggar, is quite distinct in flower and habit, the blossom of the latter, where the two sorts are growing side by side under precisely similar conditions, being comparatively small and insignificant. Margit, though the flower is pale, makes a pretty tree, especially as a bush, and in a sunny position the fruit is very bright.

Perhaps it will be equally useful to enumerate some of the varieties least valuable for the production of a display of bloom, and foremost among such come the sorts whose petals are produced, so to speak, on a long stalk, whereby the calyx is visible between the petals, and the flowers have no appearance of solidity. Golden Noble is a typical example of such a flower, and so, more or less, are Small's Admirable and Echlinville Seedling. Duchess of Oldenburg again, in addition to being almost colourless, has narrow twisted petals, which give the bloom a singularly flimsy appearance. Cornish Gilliflower, with its curious semi-pendulous habit, is not effective, and both Gloria Mundi and Winter Greening, in addition to having pale flowers, make unattractive upright trees. Some varieties, such as Worcester Pearmain, Duchess's Favorite, &c., are gay enough in autumn with their brightly coloured fruit, but the flowers of these and the following are mostly poor and pale in colour: Gipsy King, Golden Harvey, Queen Caroline, Alfriston, Washington, Scarlet Golden Pippin, Red Quarrenden, Old Nonpareil, Mannington Pearmain, and Ribston Pippin, which is also very subject to canker. Cox's Orange Pippin, the best of the dessert Apples, though free and constant, is not among the most conspicuous in bloom, but it seems little short of impious to criticise such a delicious fruit as if it were a mere flowering shrub, and it may be suggested that Cox's Orange Pippin should be abundantly planted where it can have the full sunshine, when the fruit will assume a brilliancy of colour that will quite compensate for the lack of brightness in its flowers. T. W. G.

Late keeping Apples.—Notwithstanding the value of early Apples the late varieties are far more so, considering that when the former are in use there are so many other fruits available for both the kitchen and dessert. The former could be dispensed with much better than the latter, and, strange as it may appear, there is a great predominance of early Apples in most private gardens. Take from February until June, there are few kinds of fruit available for dessert, but not so from July until Christmas. This state of things arises from two causes; firstly, from a bad selection; and, secondly, careless storing. It is quite as easy to have a good supply of first-class late Apples as early, if care is taken, as there are plenty of good late-keeping kinds. In this garden we have a good selection, many of the sorts having been planted within the last ten years, and the last two years we have had a liberal supply well into the spring or early summer.

This year, in the first week in June, we had good samples of twelve varieties. It is quite unnecessary to put them into barrels to keep them, as we preserve them in an ordinary fruit room from the time they are gathered. This is where the fruits were kept that were so well spoken of by the editor of THE GARDEN; then why go to so great an expense to provide storage accommodation!—J. CROOK, *Farnboro' Grange, Hants.*

PLANTING VINES IN JUNE.

GROWERS of Grapes by express find propagating young Vines one year and planting out the next what we term yearlings is altogether too slow, especially where the old Vines they are intended to replace have been forced early, and the house becomes ready for re-planting by midsummer. Whether or not a year is gained and Vines, grown into a fruiting condition by the time they are twenty months old, live to make centenarians, experience alone can prove, but one thing is certain, many people now adopt the method I am about to describe, and all agree in saying the system so far is satisfactory. In order to carry it out properly the planter must have the convenience for propagating and growing on his own Vines, especially when long distance separates him from the trade, otherwise the check produced by removal from strong bottom-heat which nurserymen employ might frustrate his intentions. Assuming that the house to be planted will be ready by the middle of June, well-ripened eyes should be put in in February and grown on steadily, first in, then upon a hotbed from which the young plants can be transferred to the borders when the latter are in condition for their reception. There are two methods of preparing these Vines—the first, and probably the best, being the sod system, originated and practised by Mr. Thomson, of the Tweed Vineyard, Galashiels. The second is the old plan of striking the eyes in small pots, and giving perhaps one shift to prevent the roots from becoming coiled to any extent, or what is generally termed pot-bound. Of the two, the sod system takes up the most room, as it is necessary to lay the turves Grass side downwards on the top of a bed of fermenting tan or leaves, and fill in between the squares, which should not be less than 9 inches across, with light rich soil to draw the roots and prevent them from drying out. Mr. Thomson, in his work on the Vine, says he allowed the roots to form a complete network over the surface of the turves, and some time before he wished to transfer, each sod was cut round with a sharp knife to induce the formation of several young roots wherever a main root was shortened. These plants in due course were moved bodily with a tan fork, and they grew away freely without feeling the check.

PREPARATION OF THE HOUSE AND BORDER.—Internal planting, it is hardly necessary to say, is imperative, and cleanliness being equally important, the old inside border should be removed bodily, the walls and foundations well scalded and linewashed. The woodwork also should be washed or painted. The arrangement of sound drainage on a concrete bottom then follows. The border for the first year need not be more than 3 feet in width, but it should be formed of materials that will ferment, otherwise fermenting leaves or manure must be placed against it to raise the temperature to 60° before the Vines are planted. The better to secure this warmth it is necessary to cut fresh turf some time in advance and stack secure from wet, when the fresh herbage will soon produce the desired effect, and it will be ready for chopping down and mixing with suitable correctives. These may consist of old mortar rubbish, bone-dust, or horn shavings, and lively burnt refuse from the charring yard—the most useful department in all good gardens. When ready for wheeling in, large sods, Grass side downwards, must be placed on the drainage, the border, close to the front arches or supporting piers, being kept up by narrow strips to form an inside retaining wall. The better to ensure revival of the heat, the border must not be made too firm, but 6 inches at least should be added to allow for settling; further,

as nothing succeeds like success, a lining of hot leaves where plentiful will give valuable assistance at the outset and reduce the necessity for continuous watering. When the border is ready and the Vines are transferred, they should be lightly covered with soil, moderately watered with hot water at a temperature of 90°, mulched with fresh Mushroom manure, and slightly shaded. Similar Vines from pots need not be shaken out, but the coiling roots should be picked out with a pointed stick and carefully spread out in the direction they are to follow.

AFTER TREATMENT.—If summer weather has set in and the sun produces a genial temperature, strong fire-heat will not be necessary. Still, this aid must be at command when ordinary vinery treatment cannot be maintained without it, and atmospheric moisture at first must be abundantly produced by frequent syringing with tepid water, not so much the young Vines as the border and every part of the structure. If all goes on well, shade may soon be dispensed with, and there will be a fair prospect of the Vines filling the house with stout, short-jointed canes by September, when more fire-heat may be essential to the ripening of the buds thoroughly. If the house intended for this method of planting can be got ready earlier in the spring the eyes may be put into the turf in December or January, or Mr. Wildsmith's method of making the border first and striking the eyes upon it may be adopted. On the other hand, the work may be deferred until July, and then the lower buds of the young canes will ripen fairly under sharp autumn firing. I give my first choice to June, as we then have the summer before us; solar heat and daylight are increasing, and all the Vines, including supernumeraries intended for fruiting the second year, get thoroughly ripened.

DISTANCE AT WHICH TO PLANT.—If a good hit has been made upon the propagating bed, and the small squares of turf are found bristling with tiny rootlets ready for immediate action, many may be tempted to plant thickly, fruit, and cut out duplicates, but this is a delusion, as crowding injures the Vines intended for a permanency, and very few indeed cut out supernumeraries until after they have done irreparable mischief. Close planting, if only to avoid temptation, then, should not be thought of, and the old method of putting a Vine under each of the rafters carrying 3-feet lights discarded. Better plant opposite the centre of each light, as the pruning-buds on the spurs will then get the fullest benefit of sun and light, so essential to perfect ripening. This matter of distance, however, must be governed by circumstances, the most important point being the length of rafter, which may vary from 12 feet to 24 feet. Taking the medium of 18 feet, the permanent canes should be 6 feet apart, to favour the ultimate training of two rods from each stem, and the immediate growth of alternate duplicates for giving a few bunches the following year. All the Vines may be stopped when they have made half their allotted length of rod, and those intended to remain will make roots in proportion to the leaves and laterals they are allowed to produce the first season, the second breaks, as a matter of course, being trained to the wires until they reach the apex of the house. Supernumeraries, on the other hand, must have their laterals pinched and re-pinched at the first leaf from the base to the pruning-bud, precisely the same as we manipulate Vines intended for fruiting in pots. The second leaders also may be checked, but not to an extent that will endanger the breaking of the lower buds. Fruit in preference to strong wood being the chief aim, this method of pinching will plump up the main buds, and full exposure to light and sun-heat will favour perfect maturation, the keystone of success in fruiting young Vines.

HEAT AND AIR.—I have said June planting favours growth with a minimum of fire-heat, especially in hot, brilliant seasons, but there are periods even in summer, when gentle fires are essential to the maintenance of a brisk vinery temperature, say of 65° to 70° through the night and 75° to 80° by day. Muscats, of course, require a little more heat than would be good for Hamburgs, but in order to

secure quick, solid growth of short-jointed wood, the heat must be adequate to the free admission of air without lowering the temperature. Air through June and a portion of July should be admitted at the top, the earlier the better, to let out vitiated vapour and prevent the foliage from scalding; then as solar heat increases the full volume must be balanced by opening or closing the front ventilators. From this time forward, the Vines being in full vigorous growth, the usual mode of free ventilation to consolidate the wood should be practised, but the final closing must be made to ensure a temperature of 85° to 90° with sun-heat and moisture. In due course the wood will begin to change colour, when still more air with plenty of heat and slightly decreased moisture will favour gradual ripening; but on no account must the main leaves suffer from drought or the attacks of insects.

WATER.—The new borders being narrow and more or less open to the action of the air, the top and internal side should be well protected with mulching or long stable litter. This covering, in preference to the direct syringing of the foliage, should be kept constantly moist, not only to draw the roots upwards, but also to produce a steady rise of atmospheric moisture. Water, pure and simple, will answer this purpose at first, but by degrees it may be tinged with clarified liquid and soot water. No rule can be laid down for the watering of the compost, but, considering the quantity of wood and foliage the Vines are expected to make, it is only reasonable to suppose the supplies must be liberal and frequent.

W. COLEMAN.

SUMMER PRUNING OF CURRANTS.

"J. S. W." (p. 509) says: "I am unable to see how anything but a reduced crop is gained by the summer pinching of Currant shoots as directed by 'J. G.' at p. 470;" and further states that "the Black and Red Currant shoots produced annually from the older wood almost bear at any joint their whole length, and the finest clusters are always nearest the top."

Although I have many Currant bushes, and have made a study of market fruit culture for years, I have never met with a market grower who adopts this extension system of growing Currants, and those who do not pinch in summer cut the young wood down closer than I recommended; in fact, there is no fruit, with the exception of Nuts and Filberts, so severely pruned as Currants. I am sure anyone looking at a market-grower's plantation of the Baby Castle variety, pruned to from eight to twelve main shoots, spurred in as close as a Vine, and noticing the enormous crop of bunches, would never think of adopting the other system. According to "J. S. W.'s" directions, it would need ladders to reach them after the first few years. All I said at p. 470 I still adhere to, for this reason, viz., I have tried it myself with excellent results for many years, and if "J. S. W." has not done so, I would advise him not to miss another season without giving the plan a trial. I am well aware that Black Currants may be grown successfully by leaving the young wood at full length and merely thinning out in winter, but to treat Red and White kinds in the same way is something new. Although the finest buds will, as "J. S. W." says, be always nearest the top, if left to develop full length, it will be at the expense of the old spurred-in branches, as they will soon cease to fruit altogether. On examining some bushes treated as "J. S. W." suggests, I find the last year's shoots average from 1½ feet to 2 feet in length, the bunches being mostly at the top, with a few straggling ones along the lower parts. Although the bushes thus treated soon became larger, after a few years the weight of fruit in the aggregate was more than that produced by the closely spurred-in bushes. Those who do not pinch in summer will, I am sure, cut down closer than I recommended in winter if they expect a full crop of fruit.

J. G.

Ants in vinery.—Will any reader kindly suggest means for destroying the ants with which my vinery is infested?—W. G. G.

SEASONABLE WORK AMONG FRUITS.

ALTHOUGH many growers thought some time ago that the cold weather and keen cutting winds had injured the blossoms to a serious extent, it is gratifying to learn from all quarters that fruit crops generally are likely to be highly satisfactory. Blight and grub, as a rule, blow up in myriads with the east wind, of which this season we have had more than enough, but, so far contrary to expectation, fruit trees of all kinds are remarkably free, and the young growths, though late, are healthy and promising. In the broad orchards so important to west midland fruitists the finest, boldest, and cleanest, although not the brightest, blossom I ever witnessed are now going over. Twenty-four hours' steady rain, which might have been more acceptable from a warmer quarter, has been a godsend both to the newly-set fruit and the roots of the trees, and something indeed extraordinary must now speedily happen to prevent them from giving an abundant yield. This abundance, if I may be pardoned for counting the chickens almost before they are clear of the shells, however, is of little use unless preparations are at once made for careful hand-picking and storing, as this is the only method of turning our increased Apple and Pear produce into profit. I say this advisedly, as I have seen many tons of bright fruit left to rot and sink into the ground, and wagonloads of that bright, saleable, and all-round useful Apple, Tom Putt, ground into cyder worth 3d. a gallon, when I have been selling a good sample at 6d. a dozen. Paul may plant, Apollos may water, and God may give the increase, but until this increase is preserved on a gigantic scale, English fruit growers will not stand the tithes of a chance against the colonists.

The season being late, the general routine also is late; still, work in every part of the fruit garden is crowding in, and the better to keep it in hand the good old maxim, "nothing must be allowed to stand over to the morrow if it can be performed to-day," this year will be found peculiarly applicable. Ripe fruit we may secure, but we must have ripe wood also, and those who take time by the forelock and, next to doing their work well, do it at the right time, are most likely to succeed. Turning to the walls, we find

PEACHES

growing very fast, and many of the shoots are fit for tying, nailing, or pegging in. A few more shoots may require pinching or cutting out, as it is a great mistake to lay in more than will be wanted for another year, and thinning must not be neglected. When Peaches set as they have done this season, thinning is a pleasant piecemeal business, as the trees must be looked over several times, and then, so conservative are gardeners, a neighbour might often do a good turn by putting on the finishing touch. An even spread of fruit, naturally the finest, is the main point, and possibly it matters little whether each Peach hangs from or stands upon the shoot. Oftimes choice is out of the question, but when I can have my pick I follow out my Peach house rule—point upwards to the sun 100 Peaches to 100 square feet of foliage. These brief remarks convey all I have to say upon Peach thinning, for this year at least. Some few, I believe, crop heavier, but I cannot see the utility of straining the trees in the production of stones when they might be more profitably employed in furnishing a smaller number with pulp. Our only insecticide this season has been soapsuds, followed by copious washings with the hose, and my trees never gave less trouble. Where, for convenience and the comfort of moving about with clean feet, a dusting of old lime rubble and long litter have been placed upon the wall path, the heavy crop of fruit will now justify a second addition of the latter, and sparsely foliaged trees will pay for a dash of bone-meal or guano.

PEARS

on walls, also pyramids, have set plenty of fruit, and in due course will require much thinning; meantime the most forward trees, especially on south and west walls, may be divested of gross breastwood to let in light and air, and force the sap

into the lower branches. A clean sweep at this early season is not advisable, as weak growths assist and protect the fruit; whilst strong ones from the main stems, if left alone, soon become robbers. The steady rain has brought about an acceptable change, but it came from the wrong direction to be of much use to us for cleansing heavily copped trees on the above aspects; consequently the hose has been turned on to wash off the decaying blossoms. If well-cropped trees on the Quince stock have not been mulched, timely attention, should the season turn out dry, will save much trouble. Warmth as well as moisture being essential to the full and early development of the fruit, a mulch that will not chill the roots and keep out solar heat will be found the most suitable.

PLUMS AND SWEET CHERRIES

require similar treatment, but the process of pinching over every part of the trees may be more general, especially where the young tips are touched with aphids. If black fly puts in an appearance in any part of the fruit garden, it is sure to be found upon Plums and Cherries, and these being generally trained upon the fan principle, all shoots left for laying in should be dipped before the points are injured. Tobacco-water is the favourite insecticide, and, provided it is used in a weak state, not once, but twice or thrice, until the trees are free, I know of nothing safer. When Cherries, which ripen their fruit early, appear clear of living insects, copious washing with clean water must follow, otherwise the fruit will remain dirty until the time arrives for gathering. Already our feathered friends are ready for action, but timely covering with nets before they get a taste is the only means by which they can be prevented from making a speedy clearance. At one time strong-growing sweet Cherries on our cold ground were seriously affected by an exudation of gum; lifting and replanting on a higher level did not entirely stop it, but recently I have given young trees more wall space, left more breastwood intact throughout the summer, and this troublesome disease has greatly moderated.

STRAWBERRIES

of all kinds, young and old, are blooming strong and profusely; the foliage, too, is plentiful and good—two points, provided they are well thinned and fed, which must tend to quantity and quality. Established plantations from which bulk of good average fruit is the first consideration, do not often get, if they require thinning, but younger plants, whose produce is intended for special purposes, require this attention. The process of thinning and tying, or propping up, to keep the fruit free from grit and vermin, should go hand in hand; and trapping where mice and slugs are troublesome should be vigorously followed up before their dainty food is ready for them. Where fresh stable litter is used for covering the ground between the rows, it answers best when introduced before the plants come into flower; but better late than never—this work may still be carried on, as one day's rain or a thorough washing with the hose will cleanse the straw from all impurities. Maiden plants from which forcing and planting stock is to be obtained, must not feel the want of water. If well planted last August and divested of their flower-scapes in May, runners will be strong, if not early; moreover, they will be plentiful. The mode of layering is entirely a matter of taste. Some growers layer the runners in small pots, and shift into the fruiting size as soon as they are well rooted. Others fill the fruiting pots at leisure, convey them to the ground, and save further trouble, also checks, by pegging them firmly into the compost. Each plan has its advantages and the reverse, but, provided the stock is satisfactory and the work is properly performed, either plan will ensure 90 per cent. of fruiting crowns. The greatest objection, I believe, to pegging down into the fruiting-pots is the watering, which many think sours and washes out the most valuable constituents of the compost. I always adopt this method, as I have the convenience for watering with the hose, and the plants invariably flower and fruit to my entire satisfaction.

Varieties for forcing.—With the exception of perhaps half-a-dozen sorts met with in almost every

garden, the choice of varieties, like the method of preparing them, is a matter of taste. Vicomtesse Héricart de Thury, La Grosse Sucrée, Sir Charles Napier, President, Paxton, Keen's Seedling, and British Queen stand well, and take a great deal of beating. For early work Vicomtesse Héricart de Thury for a long time stood first, but many, myself included, now give preference to La Grosse, for not only is it the first to ripen, but the fruit is much more even in size, equal in point of colour, and possibly superior in flavour.

BUSH FRUITS,

especially Currants and Raspberries, will still pay for the addition of any extra mulching that can be spared to them, also they will derive great benefit from copious supplies of water. The crops these invaluable bushes are carrying are unusually heavy, and, having escaped spring frosts, the bunches of Currants will be very fine. It will be necessary to keep a sharp outlook for the caterpillar, which, once established, soon ruins the crop, and by the destruction of the foliage injures the trees for the succeeding year. Hand-picking is tedious; poisonous insecticides are dangerous; but, applied before the fruit begins to colour, quicklime is a safe and sure remedy. If rain does not wash the bushes after the caterpillars have been destroyed, a sharp dash with the hose or garden engine will cleanse the fruit and convey nutriment to the roots. Young trees must now be manipulated and trained to suit the several purposes for which they may be required. The bush form is most frequently met with, but the Red Currant is well adapted for training into compact pyramids, which look well and can easily be protected from birds. Trained to clean, single stems, they also form handsome standards for growing in neat, dressy gardens where bushes take up too much room.

GOOSEBERRIES

here are our least promising crop. The heavy load the trees carried last year may have affected them, but the principal cause of failure must be placed to the credit of the bullfinch. In addition to our usual and hitherto never-failing preventive, a wash of lime and soot, alum water was repeatedly applied to the trees. Old nets, too, were cast over them, but all to no purpose. Gooseberry and Green Gage buds they would have, and the scarce and tardy spring favoured their depredations. Thanks to the Small Birds Act, this part of the country is literally teeming with feathered life, and nothing short of good netting in future will prevent them from clearing off the crops of fruit and vegetables they take a fancy to. Where these beautiful but voracious creatures have disfigured the trees, a general trimming of the budless wood and some thinning of the young shoots will produce a beneficial effect not only in letting in light and air, but also in restoring the bushes to a neat and compact form. A correspondent lately recommended the summer pinching of bushes, an operation quite novel to me. I approve of thinning to let in light and air, but all shoots necessary to the formation of the tree in my opinion should be allowed to grow to their fullest extent. Old Currants we sometimes top when the nets cannot be stretched to span the rows or ripe fruit is wanted early, but plenty of foliage swells the finest berries and protects them from birds having an eye for colour.

FIGS.

The thirty hours' steady rain which fell at the beginning of the month will have penetrated the borders, and a mulch of long litter whilst letting in sun-heat will keep the roots sufficiently moist for some time to come. Where the trees are grown under climatal disadvantages, plenty of wall space, thin training, and close nailing will favour the growth and ripening of fine short-jointed wood. Wall Figs must not be pinched, but damaged shoots that are not carrying fruit may still be shortened back to secure an even relay of young wood, and all suckers must be removed to give the stems the full benefit of solar heat.

GRAPE VINES

on open walls and gables this year are unusually late; consequently the ripening of the

fruit in many places is extremely doubtful. Independently of this they are well worth more extended culture, as few climbers produce a better effect. Moreover, being free growers, many a bare wall and roof might quickly be covered with their graceful and refreshing foliage. Like the Fig, they revel in heat, and for this reason they should be freely disbudded, and the shoots retained stopped at the first joint beyond the fruit. Whether this ripens or not, neatness will repay the pains bestowed upon them, and close training will favour the ripening of the wood for another year. It is not yet too late to plant unpruned yearlings from pots, and although ripe fruit may be out of the question, surplus Vines still standing in the open air should be turned out without delay. Quite recently we have turned out a number of these superfluous canes for covering and keeping cool the roof of an iron room. Each rod is trained to a single wire running from a raised bank on the south side to the ridge, all the breaks are allowed to ramble, and, judging from the start they have made, there exists but little doubt that they will reach the highest point by the end of the season. Our prime object being shade, we do not care for fruit; but of this, aided by reflected heat and the igneous nature of the soil, I do not despair, when the rods, a foot above the roof, get thoroughly established. Where ripe fruit is the first object, Royal Muscadine, Grove End Sweet-water, Black July, and Miller's Burgundy are considered suitable varieties, and in favoured localities the Black Hamburg in times past has ripened excellent fruit. Cheap glass, however, and bad seasons have dashed the ardour of hardy Grape growers, but these changes do not detract from the value of the Vine, whose fruit only is tender, for beautifying cottages, or planting against old trees in warm soils and sunny situations.

RED SPIDER.

No one will deny that this troublesome pest is very difficult to eradicate, or even to keep in check, and no one will positively affirm that sulphur-painted pipes are of any real service in destroying insect life. Owing to the coldness of the season, many fruit growers have been obliged to give much more fire-heat than usual to the Grapes, Melons, and other crops, and as bright sunshine, cold easterly winds, and heated pipes are conditions almost certain to lead to an attack of red spider, many more, no doubt, besides myself, have far too much of it to contend with. Once more we have tried painting the flues and pipes with sulphur with no better results than on previous occasions. On several evenings the sulphur fumes were so strong, that we did not care to stay in the house, and certainly were very doubtful as to their effect on the Vines. Luckily, very little harm was done to the foliage of the latter, and unfortunately none whatever to the spider. We have also tried the effect of sulphur fumes in the Melon house, but here again no perceptible harm was done either to the plants or spider, and I am of opinion that once the latter effects a lodgment it cannot really be got entirely rid of, for that season at least. Cold spring water, applied either through a hose or syringe, disturbs them and at the same time destroys many; but they soon recover from this temporary check. "Why not repeat the dose?" some will ask, and in the case of Vines cleared of fruit it is practicable enough, but we prefer to keep the bloom intact on the berries, and this is out of the question if frequent syringings are given. As regards Melons, it is not wise to frequently saturate with very cold water the soil in which they are rooting. Moreover, according to my experience, water, however often and forcibly it may be applied, will not really destroy red spider either on Vines, Peaches, Melons, or Cucumbers. Last season we grew Cucumbers on the "express system"—that is to say, without giving any air—but in spite of the very frequent overhead syringings and the maintenance of a moisture-charged atmosphere, the spider spread rapidly; in fact, appeared to delight in the treatment given. Prevention is undoubtedly better than cure, and if all were as thorough in their preventive measures as Mr. Burrell

in THE GARDEN (p. 492) appears to be, we should hear less about the mischief done by red spider. At the same time, I question if he would always be able to pride himself in having "invariably kept the upper hand of it" were he in charge of more modern houses or any largely constructed of iron. He labours under a great disadvantage in that he has so many flue-heated houses under his charge; but take away half the rafters in these structures, narrow the remainder, or substitute iron bearings, and he would find matters very much worse than they are now. I do not wish to detract in any way from the merit of having so successfully combated the dreaded spider, and merely comment on his practice for the sake of drawing attention to the fact that circumstances materially alter cases.

Sulphur is undoubtedly the best preventive of the spread of red spider, but it must be applied direct to the foliage, otherwise it is useless. Directly the spider is seen on the Vines the under side of the infested leaves ought to be well coated with flowers of sulphur, this being most cleanly when applied with a sponge. Our plan is to dip the latter first in water and then in the sulphur, no difficulty being experienced in lodging a good quantity of the latter on to the leaves. Where much of the foliage is infested, sponging all of it is a somewhat tedious operation, but more time is often spent over a few stove plants that stand less in need of sponging. In the case of Melons and Cucumbers, the quickest method of coating the foliage is through a syringe. A handful of sulphur worked through a muslin bag will mix readily with the water, and sufficient of it may be lodged on the underside of the foliage, in the course of one or two syringings, to check the spider. As a rule, spider on Peach trees may be kept in check by daily syringings, this being discontinued when the fruit is ripening. After the fruit is all gathered the foliage should be well coated with sulphur, and plenty of air being left on the house, no further trouble need be taken. I do not affirm that sulphur on the foliage actually destroys all the spider it comes in contact with, but it completely checks its spread, which is a very important gain. W. I.

GARDEN FLORA.

PLATE 601.

ANEMONE-FLOWERED JAPANESE CHRYSANTHEMUMS.

(WITH COLOURED PLATE.*)

WITH the advent of the above race of Chrysanthemums a very pleasant break was made from the stiff appearance of the older type of Anemone-flowered varieties represented in the annexed cut. The newer race, which the accompanying plate faithfully depicts, explains clearly the difference between the ordinary Anemone-flowered and the Anemone-Japanese. There are several newer varieties which are decided improvements upon those illustrated, as they possess a more defined disc, and the guard petals match better, thus more closely resembling the Japanese section, and for the information of those readers who do not know the sorts illustrated, the uppermost one is Duchess of Edinburgh, which I believe was the first to make its appearance, and at the time caused quite a sensation amongst growers and lovers of Chrysanthemums. The middle placed variety is Madame Thérèse Clos, and the other Souvenir de l'Ardene.

The varieties in this section appear to be finding favour with most people for conservatory use, and also for exhibition, and deservedly so, for when well grown they are very attractive. When the newer varieties first made their appearance upon the exhibition stage they caused such a favourable impression, that many feared they

* Drawn for THE GARDEN in Royal Exotic Nursery, Chelsea, Nov. 20, 1886, by H. G. Moon, and printed by G. Severeys.

would elbow out the older varieties of Anemone-flowered varieties; but, now that the various Chrysanthemum societies are providing special classes for them in their schedules, there is no fear of this being done. The colours of some of them are so chaste, and the characters so distinct, that they cannot well fail to become great favourites. A good yellow variety is much needed, as that colour is indispensable to give the necessary effect in a stand of cut blooms. A pure white variety would also be welcome, as at present the list of sorts is but short, but, no doubt, in time other kinds will be raised. There are several methods of cultivating the plants, but the way in which the forms of the flowers, as also the colour, may be obtained is that adopted for the production of large blooms. Some of the varieties do well trained "bush" fashion, as they flower very freely, and make splendid objects for the conservatory.

Many people think that they are more difficult to grow than either of the other sections, but I have not found them at all capricious, constant attention being the most important matter.

Anemone-flowered Chrysanthemum.

Those wishing to grow this charming race of Chrysanthemums cannot do better than procure good plants by cuttings in the usual way, and grow them on without a check. If this is done, no difficulty will, I think, be experienced with them. It must be borne in mind that the attention paid to them during the months of June, July, and August must be unremitting; that there be not the slightest neglect in watering and carrying out other details.

I find that the Anemone-Japanese varieties can be more heavily cropped than any of the other of the large-flowered sections. The buds should not be selected too early, as thus the flowers are liable to become coarse in the petal, and the centres do not develop so well as when the buds are formed later, and the colours also are, as a rule, much paler. From the end of

August to the middle of September is a good time to select the flower-buds in the south of England, but further north they may be selected a little earlier.

I append a list of the best kinds:—

FABIAN DE MEDIANA.—I consider this the best of the type. The guard petals hang almost perpendicular from 3 inches to 4 inches long, of a soft shade of pink striped with a deeper tint; the disc or centre is high and full, of a rosy lilac shade tipped with white. It is a strong grower.

MADMOISELLE CABRIOL.—A large flower, having long flat guard florets of a delicate bluish colour, which sometimes incurve, giving it quite a novel appearance; the centre lilac.

SEUR DOROTHEE SOUILLE.—Fringe petals pale lilac, centre very high and wide; white shaded rose, fading with age to nearly white. This when well grown ranks as one of the best.

MADAME CLOS.—Guard florets flat or strap-shaped, of a beautiful rose-violet; centre full, white shaded with lilac and tipped with yellow. This variety, one of the earliest, is of excellent habit and constitution, and produces blooms in great quantity.

MADAME BERTHA PIGNY.—Rose-magenta guard florets, centre of the same colour. A full, large flower.

SOUVENIR DE L'ARDENE.—Guard florets deep lilac, centre paler. Fine bold, solid flower.

BACCHUS.—Rich velvety crimson, reverse of petals silvery white.

RATAPAIL.—Buff or dull brown, with long guard florets and a medium-sized disc. On account of its peculiar colour it should have a place in this section.

MARGUERITE VILLAGEOISE.—Deep lilac, centre full, of a lighter shade. Very free flowering.

DUCHESSE OF EDINBURGH.—Guard florets bluish white; centre lilac outside, with a yellow inner ring. A medium-sized flower.

MADAME THERESE CLOS.—Guard florets rose-violet; centre disc, which is very thin, yellow.

STOVE AND GREENHOUSE.

T. BAINES.

TETRATHECAS (TREMANDRAS).

THOUGH the individual flowers of the Tetrathecas lack the size and brilliancy present in those of some plants, this is compensated for by the profusion in which they are borne, the length of time they remain fresh and effective, and the long succession that is produced. The distinct character of the flowers, and also the graceful habit of growth of the plants, make them worthy of general cultivation. There are two forms of *T. ericifolia*, the Heath-leaved species, one in which the foliage is thickly clothed with hairs, in the other the leaves are glabrous; in other respects there is not much difference in their appearance. Both forms used to be much grown for exhibition, as when the specimens had attained a considerable size and were well managed, the innumerable flowers with which their slender shoots were densely clothed, combined with their distinct colour and form, always made them conspicuous objects.

T. verticillata, is a smaller growing species, with slender drooping shoots and very narrow leaves. The flowers are produced freely from the base of the leaves almost from end to end of the shoots, and are much larger than those of *T. ericifolia*; the colour is a combination of violet and red. The plant keeps on blooming freely and almost continuously from spring to autumn, on which account it is very useful in a small state. This species does not attain a large size, an example that is from 2½ feet to 3 feet in diameter may be looked upon as a large speci-

men. It used to be often met with on the exhibition stage, but now, like the Heath-leaved species, is seldom seen either in the exhibition tent or in the greenhouse. That both are so little grown for decoration may seem strange, as they flower so freely when quite small. In addition to their other desirable properties these Tetrathecas are by no means difficult subjects to deal with, as with fair attention they will last for many years, not being so liable to die off suddenly as some plants.

Both the species are easily propagated from cuttings made of the points of the half-ripened shoots about August. The cuttings should be put in an inch or so apart. Six-inch pots are the handiest size; these ought to be well drained and half filled with a mixture of fibrous peat and sand, finishing off with pure sand. Insert the cuttings and cover with propagating glasses that will just fit inside the pots. An intermediate temperature or a few degrees more will answer better than keeping them warmer; shade will be needed when the weather is bright, as cuttings of these plants, in common with others of a like nature, should be stood well up to the glass, or they are liable to damp. To avoid this, the propagating glasses should be frequently taken off and wiped out. Care must be taken that all decayed leaves are at once removed, as if this is not attended to many of the cuttings will be lost. If all goes on satisfactorily, the cuttings will root during the autumn, but it will be well to defer potting them off till spring. When there are indications of roots being formed tilt the glasses a little, increasing the air gradually until they can be dispensed with altogether. As soon as the cuttings are fairly rooted they will begin to push top growth; when this has made a little progress pinch out the points. This should not be neglected, as it is necessary to thus encourage the formation of sufficient shoots to furnish the plants at the base. Give gentle growing warmth through the winter. About April move them singly into small pots; a mixture of fine sifted peat and some sand suits them well. It will be well to keep the atmosphere somewhat close until the roots begin to move. Stand the plants where they will get plenty of light on some moisture-holding material, as without this the small amount of soil which the pots hold is liable to dry up so quickly that there is danger of the plants getting injured. Watering must be attended to, as if the roots were to become so dry as to cause the shoots to flag, the plants would suffer. A moderate amount of air must be given, regulating the quantity admitted according to the state of the weather; when it is hot, water should be thrown about freely on the floor of the house or pit where the plants are growing, so as to prevent the atmosphere getting too dry. Close early, syringing slightly overhead at the same time. Enough progress should be made by the middle of July to allow the plants to be shifted into 3-inch pots; give soil of a similar character to that advised for the first potting. Tetrathecas are fine-rooted subjects that, from the cutting state onwards, seem to do better in peat than loam. As the growing season draws to a close, disperse with shading and discontinue syringing overhead, giving more air so as to ripen up the growth.

It will be well to keep the temperature somewhat above that of an ordinary greenhouse, which will suffice for them when they get older, as, like most hard-wooded plants of the same age, they do not like being cold. Before top growth begins in spring shorten the shoots back, removing about half the length that was made after they were stopped, and again in

April give a shift. They are free rooters, especially the Heath-leaved species; pots 3 inches larger will not be too big if the plants are well rooted. For this potting the peat ought to be used a little rougher and the plants potted firmly. As soon as growth commences the strongest branches should be tied out horizontally to ensure well-furnished bushy specimens. Treat generally in the matters of light, water, and shade as in the previous summer, still keeping the pots on a moist bottom. After potting, withhold air until the roots begin to move, when more will be required than was given in the preceding summer. A second shift will not be needed this season, but soon after mid-summer the shoots should have their points pinched out; keep the branches well tied out; this is more necessary with both forms of the Heath-leaved species than it is with *T. verticillata* on account of their denser growth, which should be kept sufficiently open to admit of air and light getting to the centres of the plants; if means are not taken to secure this, the foliage will be deficient in substance and liable to become a prey to mildew. Treat during the summer as before recommended; towards the end of August little, if any, shade should be used, neither should the syringe be employed, the object being to get the season's growth matured. To further assist this, give more air, keeping the atmosphere drier. Through the following winter a night temperature of about 40° will be sufficient. A few sticks will be required, but only sufficient to support the principal branches, leaving the weaker ones to hang loose.

The free-flowering nature of the plants is such that even in this size they will bloom profusely. Where plants of a larger size are required without delay, it will be necessary to again shorten the shoots back in spring. By so doing the flowers will be sacrificed, but where the plants are wanted for ordinary decoration it would be a mistake to lose the bloom, as even at this stage they will have a pretty appearance. The two varieties of *T. ericefolia* will begin to open their flowers in the early months of the year, according to the temperature they are kept at during the winter. They will go on blooming for eight or ten weeks, after which cut the shoots back as before, and as soon as they have broken move into pots about 2 inches larger. More root room should be given as it is needed until the specimens have reached a size as large as they are wanted. In roomy houses big examples, that have attained something like 4 feet in height by as much through, are very effective, as when in good condition the leaves are almost hidden by the profusion of bloom they bear, but in most cases smaller plants, say from 18 inches to 2½ feet in diameter, will be the most useful.

T. verticillata does not attain so large a size as *T. ericefolia*, but it grows freely, making longer annual shoots than the latter kind. Some growers cut the shoots of *T. verticillata* back about midsummer after the plants have bloomed for a time; in this way they are kept in a more compact condition; the second growth will flower freely later on. Before growth begins to move in spring they will require to be again cut back, after which they will push freely and bloom as before. Being a smaller grower it does not need so much pot room. Where either of the species are required for greenhouse or conservatory decoration a few cuttings should be struck every second year, so as to keep up the stock, which if not wanted large can be discarded to make way for the young examples coming on.

ASPARAGUS PLUMOSUS NANUS.

WHETHER this *Asparagus* will ever supersede the Maiden-hair Fern, as "J. C. B." in THE GARDEN (p. 488) thinks, is doubtful, but at present there seems to be plenty of room for both, either in a cut state or as specimens in pots. One thing that will prevent this *Asparagus* being grown to the same extent as the Maiden-hair, for some time at least, is the fact that it cannot be increased so quickly, as cuttings will not strike, and though seeds are occasionally produced, such an occurrence is by no means common. It is therefore necessary to increase this *Asparagus* by division, which is a very slow process. Plants can be successfully divided at almost any season, except in the winter, but the best time for the operation is spring and early summer, as they will then become well established before the dull days set in. Although this *Asparagus* will at times push up a number of stems from the base, it by no means follows that the specimen can be divided into as many pieces as there are shoots, for on turning it out of the pot and removing the soil it will be often found that two or three of the shoots proceed from one crown, and cannot be taken off separately with any roots attached to them. As these plants require to be very carefully divided, a good way to remove the soil is on turning the plant out of its pot to place it under a tap and wash every particle of soil away from the roots. There is far less risk of breaking any of the roots by following this plan than if the earth is removed by force, as the water washes away the soil so perfectly, that there is no difficulty in tracing the origin of each shoot. After division the plants must be again potted, taking care not to use too large pots till root action recommences, and if they can be kept rather close up to that time, so much the better. A very good compost for these plants is two-thirds fibrous loam to one of leaf-mould, with a liberal admixture of silver sand. In the case of established plants, especially if they are allowed to run up a rafter or trellis, seeds are occasionally produced, and when this happens they should be gathered as soon as ripe, and being cleaned of any pulpy substance that surrounds them be sown at once.

Soil such as that above recommended for potting is very suitable for sowing the seeds, provided any large lumps are removed. The seeds will germinate readily in a stove temperature, and when large enough can be potted off. Though this *Asparagus* is regarded as the best of all, there are, notwithstanding this, several others well worthy of cultivation for their ornamental qualities, viz., *plumosus*, which differs widely from its supposed variety *nanus*, as in *plumosus* the branches form a confused mass of delicate greenery, while in *nanus* they are flat and frond-like; besides which, *plumosus* can be struck from cuttings, which is not the case with the other. The cuttings must be formed of the young growing shoots, taken during the summer months, and being dibbled into pots of sandy soil must be kept close till rooted, which, in a stove temperature, will occupy about six weeks. A *plumosus* itself is more dense and dwarfer than its so-called variety, so that the cognomen of *nanus* for this last appears to be a misnomer. Another very desirable kind is *A. tenuissimus*, somewhat in the way of *A. plumosus*, but more delicate, forming, as it does, a confused mass of such slender foliage that, especially when laden with moisture, it appears to be but a cloud of mist. This kind will bear cutting well, as it quickly makes fresh growth, and the young shoots strike root as readily as those of *A. plumosus*.

All these kinds of *Asparagus* will grow in loam, mixed with leaf-mould, sand, and decayed manure. Where grown for cutting from, they may be trained up a rafter or trellis, but all, and more especially *plumosus nanus*, form handsome little specimens in small pots. These varieties of *Asparagus* must not be passed over without mention of quite a different species, viz., *A. decumbens*, a deciduous kind that commences to grow in the autumn, and whose most ornamental stage is from then till spring. It is seen at its best when drooping from a shelf or in

some such spot, when the long shoots, clothed with delicate bluish green foliage, have a very pretty effect. H. P.

GLOXINIAS AT HETHERSETT, STREATHAM.

THE display of these plants at the residence of Mr. R. Hyatt is just now one of marvellous beauty, and probably the finest ever seen, as far as size of bloom, shape, and substance, and rich and varied colours are concerned. Mr. Hyatt and his gardener, Mr. Luff, have for some years made a speciality of the *Gloxinia*—first breeding for size; after this had been secured, shape and substance had to be obtained, and for the last year or two varied colours have been the chief object in the crossing and intercrossing.

In a long Peach house are a quantity of young seedlings bearing between 3000 and 4000 flowers, each from 3 inches to 4 inches across, and of almost every conceivable shade of colour, from pure white, pink, clear rose, crimson-maroon, lilac, purple, magenta, scarlet, purplish black, &c., some profusely spotted in the throat and on the limb, and some having the limb heavily marked with colour and destitute of spotting. These plants are all seedlings of this year's growth; the seed was sown on the 1st of January, and the plants have been grown on rapidly in strong heat ever since. They are now strong plants in 4½-inch pots, with tubers the size of a large Pea, bearing large, handsome leaves and an average of six flowers. In another house are a quantity of two-year-old plants in larger pots, bearing a profusion of leaves, and about fifty flowers open on each plant. These produce a charming effect. The soil used for these plants is a mixture of loam, leaf-mould, and decayed manure in about equal parts, adding a little sharp sand, but no peat. When the plants have become pretty well established, they are occasionally watered with liquid cow manure. The fish manure is very injurious to *Gloxinias*, causing the leaves to curl and put on an appearance of being scorched, and producing deformed flowers. *Gloxinias* are often staged at public exhibitions, but they are seldom seen to advantage, as, however carefully packed, the flowers, owing to their soft and fleshy character, do not travel well. To see them in their pristine beauty they must be seen at home. Their blooms are useful for cutting and for mixing with other flowers, and last fairly well in water. W. H. G.

Stephanotis floribunda.—This well-known plant is a general favourite, but it is perhaps not so generally known that it can withstand a great amount of cold uninjured, or, at any rate, without impairing its flowering properties. An example of this may be seen in Mr. James's nursery at Norwood, where a large plant is covering the roof of a house. Through an accident to the heating apparatus in the very severe weather last winter this plant became frozen, and was without any warmth for some days. After it had been frozen, the house was covered up and kept dark in order to thaw the plant gradually. The plant is now in the most vigorous health, and laden with thousands of trusses of its fragrant blooms.—W. H. G.

Nepenthes.—These plants are remarkably well grown by Mr. James in his nursery at Norwood. These plants are suspended from the roof of an ordinary stove; in fact, Mr. Clarke, who has the management of them, says: "I pot the *Nepenthes* in the same kind of soil that I use for *Dracenas*, that is, loam, leaf-mould, peat, and sand. They get little or no shade, and I find them produce the greatest amount of pitchers in a rather cool house." The latter statement we can endorse from experience, but it is a somewhat fresh experience to know that these plants grow freely and their leaves remain of a deep rich green colour growing in loam. Some of the kinds thus treated are *N. Hookeri*, *Rafflesiana*, *Dominiana*, *robusta*, *hybrida*, *Mastersiana* in several distinct forms, and various others.—W. H. G.

Ericas blooming at Norwood.—It is very gratifying to find these plants reviving in the public

estimation after being neglected for so many years. We recently observed a large number of kinds flowering with Mr. James, who appears to manage these and other hard-wooded plants in first-rate style. Amongst the kinds now blooming especially notable are huge specimens of the yellow-flowered *E. Cavendishi* and the more compact-growing *E. depressa*, the beautiful tricolour-flowered *E. Massoni*, *E. eximia*, *Candolleana*, *Bothwelliana*, tricolor rosea, *ventricosa tineta alba*, *coccinea minor*, *brevifolia*, *grandiflora*, and various others. These plants for the most part are standing in the open air fully exposed to the sun, and treated thus the flowers become more highly coloured, and they retain their beauty for a longer period than when the plants are shaded; at the same time, the pots in which the specimens are grown should be screened from the fiercest sun, otherwise the roots are apt to suffer by burning.—W. H. G.

Laced Auriculas.—If "A. D." refers to THE GARDEN, May 21 (p. 468), he will see that he does claim to have introduced them. Now, he says, he makes "no claim as to the original introduction" of them. I asked if they were Vilmorin's strain, and whether they were procured from Chiswick? Why could he not answer this in order to settle the question? At Mr. R. Dean's request the committee of the National Auricula Society allowed what he termed laced Auriculas to be shown with the "fancies." Now "A. D." complains that the judges give the prizes to "nondescripts," and pass over his laced flowers. All I can say to this is, that the best judges in the country judge at the Auricula shows, and their decisions are usually accepted as being correct. The so-called laced Auriculas are alpine, differing from the ordinary strain not so much as Belgian Pansies differ from the show Pansies. They can compete in all the alpine classes, and when "A. D." has improved them as much as Mr. Turner has improved his strain, they will be likely to take a higher place on the exhibition table. It will take years of careful selection to do this.—J. DODGLAS.

Ivy-leaved Pelargoniums.—These have of late years been vastly improved, and now we have varieties in all shades of colour with the graceful trailing habit of the old Ivy leaf. These are remarkably useful basket plants, as when trailing down and throwing out their long flower-stalks they are seen to great advantage. For covering trellises or training up columns in the conservatory few plants can excel them, and in the flower garden, large vases, flower baskets, and raised beds can hardly have a more graceful edging than the Ivy-leaved Pelargoniums. For supplying cut flowers I find the double and semi-double kinds most useful, and the way we manage to get a supply of bloom is to put some old plants into pots or boxes at the foot of back walls of plant or fruit houses, and stretch some wire netting along the face of the wall to support the shoots. The way they keep on flowering if liberally supplied with liquid food is surprising. Where cut flowers are in great request it will be found a most useful addition to the supply if a good batch of these plants is kept under glass all the season, as they are then much clearer in colour. They are of the easiest culture, and little affected by insects. They ought certainly to receive more attention than is usually accorded them.—J. G. H.

SHORT NOTES.—STOVE AND GREENHOUSE.

Medinilla magnifica.—This is blooming splendidly in the Victoria house at Kew. The rose-coloured flowers are produced in pendulous racemes, and they last in perfection for a lengthened period. The foliage is also ornamental.—E.

Seedling Begonias.—Flowers of these from Mr. Christian are of splendid colour and large size, showing what has been accomplished by the florist in the development of this flower.

Bermuda Lily (*Lilium longidorum* Harris).—This is useful for growing in pots early in spring. The plants can be brought into flower with great ease. This Lily should be grown by all who want plants for indoor embellishment, and must be highly valuable for those who have to provide material for the London season.—J. CROOK.

Blue African Lily (*Agapanthus umbellata*).—I have thoroughly tested the frost-resisting powers of this plant, and find that it succumbs to winters of ordinary severity,

and if it is not killed outright requires the summer to recover. I left a specimen out last winter. It was planted in light soil in a sunny, warm position, but was so severely crippled as to be of no further value. In future I shall adopt cold frame treatment. I have penned this note because the African Lily is considered by some to need no protection in winter.—T. W.

Streptosolen Jamesoni.—Among the many plants useful for cutting as well as for decoration in the house this holds a foremost place. It is of free growth, free flowering, and stands well when cut. To see it at its best it wants to be grown as a standard. If the growth is well ripened in the autumn, the grower will be repaid with one of the most handsome plants of recent notice.—J. CROOK.

Anthurium Scherzerianum fasciatum.—I forward for your opinion two spathes of *Anthurium Scherzerianum* with a leaf of the plant. The peculiarity is the form of the spadix, which is always the same in this variety. Is the distinction of any commercial value?—T. C. A.

The spadix is curiously fasciated towards the top, which does not add to its beauty. Although exceedingly curious, we do not consider it bears any commercial value.—Ed.

SEASONABLE WORK IN PLANT HOUSES.

ZONAL PELARGONIUMS.—These plants are very often seen grown in such quantities as to exclude things that are more varied and interesting. When massed together in a greenhouse in large numbers in summer, the idea that presents itself is that the display is only another phase of bedding which may be done as well out of doors. The season most appropriate for these flowers is in winter, when there are comparatively few plants in bloom, and when their flowers are useful for cutting. The great market growers strike their plants late, having them much smaller at the end of summer than is usual in private places, but their houses are so constructed that the plants are close to the glass; this enables them to flower freely under a comparatively high temperature. If an attempt were made to bloom plants on this method in the badly lighted houses often met with in private gardens, they would grow more to leaf than flower; it is therefore safer to depend upon older plants that have their wood hard and matured. These may consist of cuttings struck last autumn, or older examples that have been cut back. They should now be stood out of doors in a moderately open situation, giving sufficient water to keep them healthy and the growth moving slowly. They ought to be rather under than over-potted, and manurial stimulants should be given sparingly. Prepared in this way the plants will give double the amount of bloom when placed in heat that those having their growth insufficiently matured will do. The large-flowering varieties are liked by some, but the most suitable sorts are those that bloom most profusely and have the individual flowers comparatively small.

GESNERAS, TUBEROUS-ROOTED.—These deserve more attention than they now receive. They are easily managed, free and certain bloomers, and of compact habit. They are very suitable subjects for those who have limited glass accommodation. They are not difficult to propagate, yet they cannot be increased so fast as the scaly-rooted section. One method of propagation is by division of the tubers early in spring, just after the plants have started into growth, securing to each of the severed pieces a bud or shoot. The readiest way of increase is by striking the shoots, which should be taken off when 2 inches or 3 inches long. This may be done either early in spring as soon as the shoots have attained sufficient size, or in the summer after the plants have flowered. Most of the kinds if given enough warmth and moisture, push a second growth that will bear flowers later on. Where it is desirable to increase the stock, advantage should be taken of this second growth. The shoots strike readily in sand, kept warm and moderately close and moist, but these two latter conditions must be regulated by the admission of a little air, otherwise the succulent stems and soft young leaves are liable to decay. The cuttings should be put singly in small pots; treated as described, roots will soon be formed. When this occurs, remove the young plants from the cutting-frame, and stand them where they will have enough light. After they are fairly established, move into 3-inch or 4-inch pots. A compost, consisting of about three parts loam to one of leaf mould, sifted fine, with a good sprink-

ling of sand, will answer. Give plenty of warmth and sufficient moisture in the atmosphere, and as much water as will keep the roots fairly moist, but not too wet. Late-struck stock such as this will not make so large tubers as the plants propagated earlier, but, if carefully treated, they will attain sufficient size before winter to enable them to flower nicely next summer. If the tubers are not kept too cold in winter, the plants live to attain a large size.

GESNERAS, LATE FLOWERING.—*G. exoniensis*, *G. zebra*, *splendilissima*, and others of the late blooming division when well managed make a brilliant display. The plants should now be placed where they will have plenty of light to induce a satisfactory leaf growth. Enough shade in bright weather must be given to prevent the foliage becoming scorched or discoloured, care being taken to keep them quite free from mealy bug, which, once it obtains a hold, is difficult to remove without injuring the leaves.

ACHIMENES.—These plants are often too much crowded in the pots or baskets in which they are grown, the result being that the lower leaves often become brown and unsightly before the plants have finished blooming, and the flowers are not freely produced. They may be kept in presentable condition by the use of manure water. If this is applied in a weak state it may be given every time the soil requires moistening.

GLOXINIAS.—Young plants raised from seed sown in the early months of the year should now be coming into bloom. If at all under potted feed them liberally with weak manure water, which will enable them to keep on flowering much longer than would otherwise be the case. Old examples that were started early and are now carrying a full crop of bloom will produce successional flowers more or less in proportion to the help they receive from liquid manure. It is worth while to prolong the blooming as much as possible rather than let the plants go to rest immediately the principal display is over. To keep Gloxinias flowering it is necessary to preserve the foliage in a healthy state and free from thrips or red spider. Plants raised from seed sown later and intended to bloom later on in the season must not be cramped in too small pots, otherwise the flowers will be few in number and soon over. The more light they receive the better they will bloom, and the more useful will the flowers be when required for cutting. Where the growth is stout, with thick leathery leaves, the flowers remain in good condition for several days in water, but if the plants are badly managed the flowers are useless for cutting, flagging as soon as severed from the plants.

ATACCIA CRISTATA.—This plant has singular flowers, and on that account deserves cultivation. The room that even a large example of this *Ataccia* requires is very limited. It requires stove treatment all the year round, otherwise it may be lost. It can only be increased slowly. When the specimens are strong, side-shoots appear on the fleshy stem, usually below the leaves. After a time they produce roots that would ultimately descend into the soil if given sufficient time; and where large examples are required they may be allowed to remain until the plant consists of a number of crowns. Where the object is to increase the stock, the side-breaks, when furnished with young roots, should be taken off. The summer will generally be found the best time for separating them, and the severance must be effected with a clean cut, as the fleshy succulent nature of the stems is such that, if bruised, the chances are that decay will follow. Place them singly in 4-inch or 5-inch pots, well drained and filled with turfy peat, from which some of the earthy matter has been removed, add a fourth part of broken crocks with some sand, insert the suckers so that their roots are quite covered, and secure them with a couple of sticks and ties so as to make them firm. Until the roots make some progress it will be necessary to keep the plants a little close, but this must not be carried too far, or the stems will be apt to rot. As soon as the plants become established expose them fully to the air of the house. A fair amount of light is necessary, but

shade carefully from the sun; if this is not attended to the leaves will get injured. In the course of time, as the bottom leaves die off, the stems of the plants become bare, and each year in the growing season these emit roots. If some *Sphagnum* is tied round the stem, the roots will soon take to it, after which the head with the roots may be taken off and potted. If kept moderately close for a few weeks they will soon become established. This is a good time for dealing with such plants, as there is sufficient time for the stools to break. If strong, they will form several crowns which may be either taken off when sufficiently strong to be grown singly, or may remain to form large specimens.

T. B.

PROPAGATING.

EPACRIS.—The genus *Epacris* is a very extensive one, yet there is but little difference in the propagation of the various kinds, though some are more difficult to strike than others, the very succulent growing kinds being the worst in this respect. A very good way, and one that is successfully followed by many growers, is, after flowering, to shorten back the old plants that are required to furnish a supply of cuttings, and keep them rather warmer than they have been accustomed to, the result being that the plants start rapidly into growth; but the shoots are rather weaker than would have been the case if the plants had been grown in the usual temperature. This weakening of the shoots by keeping them somewhat warmer is of great assistance to the propagator; indeed, without this some plants could scarcely, if at all, be struck from cuttings. When the young shoots are a few inches long is a good time to take the cuttings, and in selecting them, a great point to bear in mind is that the weaker shoots strike far more readily than the stronger ones, and for this reason, it is possible to take a crop of cuttings from a plant without detracting from its flowering qualities if the strong shoots are allowed to remain untouched and only the smaller selected as cuttings. As the young shoots of *Epacris* are very delicate, it is better to cover them with a bell-glass when inserted as cuttings, and on that account the size of the pots employed will depend upon that of the glasses at disposal. The pots must be quite clean, but if new, they should be soaked in water before using, for, being mostly made of porous clay, they will absorb nearly all the moisture. Thorough drainage must be ensured, and a good way to carry this out successfully is to invert a small pot over the hole of the one intended for the cuttings, and surround this with broken crocks, gradually decreasing in size till those at the top are no bigger than Radish seed. The pot should be filled in this manner to within an inch of the top; then over this the soil, consisting of very fine sandy peat, must be pressed down firmly, leaving just sufficient space for a thin layer of sand on the top. Then a moderate watering should be given, and before putting in the cuttings the bell-glass should be placed in position and slightly pressed down, in order to leave the imprint of its rim on the sand as a guide for inserting the cuttings, for if sufficient space is not allowed, they are very liable to be crushed down and broken. The cuttings must then be prepared by being cut off cleanly and have a few of their bottom leaves removed. For this purpose either a very sharp knife or a pair of scissors must be used, but in either case the greatest care must be taken that the leaf is cut off in a clean manner without any bruising or tearing of the bark. The cuttings, having been prepared in this way, should be dibbled in firmly, and as the shoots are very slender the dibble employed for the purpose need not be a large one, for the finer it is the less disturbance of the soil will take place. In either case a great point to bear in mind is that the cutting reaches the bottom of the hole prepared for its insertion, and that the soil is closed firmly round. After this a thorough watering must be given, and the pots may be allowed to stand a little while before the glasses are put on, in order to dry up some of the superfluous moisture. The pots may then be placed in a

shaded part of a house where there is a little artificial heat, or they may be stood in a cold frame, in which case the most successful treatment is to allow them to stand there till callused, when, if removed into a gentle heat the formation of roots is greatly accelerated. Very careful attention will need to be bestowed upon these cuttings during their different stages in the matter of watering, shading, &c. The bell-glasses should be removed every morning and wiped dry, as too stagnant an atmosphere will cause the cuttings to damp off, and at the same time the conditions most favourable to the success of the operation are not too damp a spot nor too heavily shaded, but it must be so situated that the soil does not dry up rapidly. When the glasses are taken off a good opportunity thus presents itself to remove any signs of decay, and also to observe if any of them are in want of water. Should they be so, it is possible to moisten the soil without wetting the foliage, by replacing the glass and pouring the water around the outside of it, for in this manner the water will percolate through the whole of the soil without so much as disturbing the sand on the surface. A point worthy of consideration is, that as the delicate shoots flag so easily they must be put in as soon as possible after being separated from the parent plant. As the cuttings root, which may be known by their commencing to grow, a little air must be given by tilting the bell-glass, and this may be increased till the glass is altogether removed.

In potting off, small well drained pots must be chosen, and the soil best suited is sandy peat passed through a sieve with a quarter of an inch mesh. The young plants should, after this operation, be kept rather close and shaded till again established.

MONTBRETIAS.—The plate of these plants which appeared in *THE GARDEN* (May 28) reminds one how easy they are to increase, for not only do they push forth offsets, and may be thus propagated by division, but should it be desired to increase any particular plant to the fullest extent (which in the case of new ones will often happen), if the bulb be potted when dormant and placed in a greenhouse, it will soon after Christmas start into growth, and, generally speaking, push up not only a flowering tuft from the centre, but several underground shoots, which generally reach the side of the pot and then come up around the edge. As soon as this takes place, the plant may be turned out of its pot and the soil removed, when in most cases it will be found that these minor growths have along their underground stem, by which they are connected with the parent bulb, produced a few roots. These may be cut off close to the bulb and potted in small pots; but in order to get the growth in the centre thereof, it will be necessary to twist the stem, should it be a long one, around the pot. So treated they will grow very well in an ordinary greenhouse and soon become established, so that by the end of spring one may have from six to twelve plants the product of a single one, and where rapid increase is an important item this is a great consideration.

DIEFFENBACHIAS.—These ornamental-foliaged plants can be readily increased by cuttings, and, what is more, they make rapid progress during their earlier stages. Should any plants run up rather leggy, the top may, without fear, be cut off and inserted as a cutting. A good and, at the same time, simple way is to stick it in the Cocoanut refuse, which usually forms the plunging material in a propagating case. The naked stems may be cut up into lengths of 3 inches or 4 inches, and also laid in the fibre or in pans of sandy soil, but in either case the young plants are not long in making their appearance, and are soon large enough to pot off.

STYRAX JAPONICA.—This beautiful hardy shrub proved itself by no means readily propagated till last season. Having a large specimen in a gentle heat for the sake of hastening the expansion of its Snowdrop-like flowers, I tried the experiment of putting in the cuttings after the manner of *Fuchsias*. The experiment was quite justified by the results, for the greater part of the cuttings struck, and when established in little pots were

planted in the open ground, and are now doing well, the spot chosen for them being one protected from drying winds. T.

BOOKS.

THE FUNGUS HUNTER'S GUIDE.*

A FEW weeks ago "The Text-Book of British Fungi," by the author of the "Fungus Hunter's Guide," was noticed in *THE GARDEN*. The remarks printed in reference to the first book apply to the second, as the new and smaller work is a kind of supplement to the larger Text Book. "The Fungus Hunter's Guide"

Grey Cantharellus (*Cantharellus cinereus*).

contains a series of keys to families, orders, genera, and sub-genera of the larger fungi, illustrated with small illustrations of each genus and sub-genus. When the genus and sub-genus is at last found by these keys, a few typical specific types are briefly described.

Works with a similar aim have been published in England before, notably "The Clavis Agaricinorum," in English (illustrated, 1869), by the writer of these lines, and "The Clavis Hymenomycetum," in Latin (not illustrated, 1878), by Messrs. Cooke and Quelet. Keys to the various sections of fungi are also found in Cooke's "Handbook," and in Stevenson's lately-published "British Fungi," to say nothing of the keys in Fries' "Hymenomyces Europaei." Mr. Hay's larger work was fur-

The Sparassis (*Sparassis crispa*).

nished with a glossary of terms (one of the best parts of the book), but in this new book, which is full of botanical terms, no glossary is given; perhaps the omission was necessary, but it pre-supposes a knowledge of all the terms used.

The plan of "The Fungus Hunter's Guide" is founded on that of Cooke's "Handbook," published sixteen years ago. This is to be regretted, as since 1871, Fries—the founder of the entire system—has published his latest and most matured views ("Hymenomyces Europaei," 1874), which views have been generally accepted by mycologists. If Mr. Hay will turn

* "The Fungus Hunter's Guide." W. Delisle Hay, F.R.G.S. London: Swan Sonnenschein, Lowrey and Co.

to Fries he will find considerable alterations and additions, genera and sub-genera of fungi added, and other genera and sub-genera obliterated. It would obviously have been better to have given the matured system of to-day, as approved by the greatest master of mycology, in preference to Dr. Cooke's plan (founded on the earlier writings of Fries) of sixteen years ago.

Keys are always difficult pieces of work, for the reason that they attempt to give definite boundary lines between genera and sub-genera when it is notorious that no such boundary lines exist in Nature. In fungi the characters of the genera and sub-genera shade off into each other, and blend in various directions. In the *Dermium*, for instance, not only do the sub-

Horny Calocera (*Calocera viscosa*).

genera blend with each other, but they shade off into the distant genus *Cortinarius*. In *Collybia* the species shade off into the distant genus *Marasmius*, and *Clitocybe* and *Tricholoma* are bounded by no distinct lines. The keys, therefore, as given by Mr. Hay, although undoubtedly useful, are full of pitfalls for beginners. There is not a genus or sub-genus without exceptions. For instance, the "ring" or collar round the stem is said by Mr. Hay to be "pronounced" in *Armillaria*, but in *Agaricus melleus* it is often totally absent; under *Hebeloma* the stem is said to be ringless, but in *A. fastibilis* there is often a ring. The gills in *Lepiota* are often "remote or free," but they are also often adnexed (or not free), and in the same manner exceptions might be pointed out in every genus and sub-genus of fungi. As was said before in THE GARDEN, the newly-invented popular names are absurd, and the attempts to

The Tiger-tuft (*Lentinus tigrinus*).

replace some of the older descriptive terms by new (as *pileus* for *hymenophorum*) are failures, and must lead to confusion.

It cannot be doubted that Mr. Hay is well acquainted with many of the fungi he describes, but his list of edible species sadly needs revision. For instance, *Agaricus cristatus*, a small fungus with a horrible odour, is said to be edible, so is *A. melleus*: this latter fungus has been known to cause constriction of the throat. *A. enosmus* is termed "doubtfully poisonous," although, on the authority of Mr. Berkeley, it

once made a schoolmaster "exceedingly ill." This schoolmaster, says Mr. Berkeley, made a mistake. Schoolmasters and "professors" seldom make mistakes. *A. squarrosus* (the smell of

Zoned Lactar (*Lactarius zonarius*).

which makes many people shudder with horror) is said to be edible. *Boletus rubinus* is said to be "suspected poisonous;" but why, or by whom? It has only been seen once or twice. *Polyporus fomentarius*, as hard as Oak when mature and as tough as leather when young, is said to be edible; so is the leathery *P. squamosus*. The "dry rot" fungus is said to be "doubtfully edible." Fancy the mental condition of a man capable of cooking and eating the hideous "dry rot fungus." *Exidia glandulosa*, a shivering mass of repulsive-looking black fungoid jelly, is not the "Witches' Butter" of some country folk, as stated by Mr. Hay. The yellow, *Tremella mesenterica*, is "Witches' Butter." Several of the smaller puff-balls are given as edible, but an instance is known where an experimenter was nearly killed by

The Peg-top (*Gomphidius glutinosus*).

eating an exceedingly small portion of one of them in a raw state. These instances would not have been quoted here had not Mr. Hay's later book differed somewhat from his former. The new book should be purchased by everyone who has the "Text-Book." Amongst specially good edible fungi, Mr. Hay gives *Hydnum imbricatum*. This is a very nasty and exceedingly tough fungus. On turning to the handbook, Mr. Hays says "it is apt to be tough;" he calls it the "Sealy Urchin;" it makes, as we think, a very hard and "scaly" repast.

The illustrations are those from Dr. Cooke's "Handbook" trotted out once again. The block of *Strobilomyces* seems to have been lost, and this is a good job; the name is therefore now put in parenthesis, as if (the venerable but once gone) the fungus itself had also nearly dropped out of existence. By the courtesy of the publishers we are enabled to print six of the little illustrations of genera drawn and engraved from Nature many years ago by the writer of this note. Other of the illustrations are, however, none of the writer's; some are half his and half someone else's; a few are atrocities by unknown "artists," as *Dedalea*, *Phallus*, *Cynophallus*,

&c. In several instances the illustrations do not answer to any of the described species, and no names are given. One figure at any rate is not British, and, therefore, not likely to be found and identified. Dr. Cooke did not print names under his illustrations of the sub-genera of *Agaricus*, but if Mr. Hay had referred to the writer's previously published "Clavis *Agaricinorum*," he would have seen names for every one. The large original drawings with names have been for several years exhibited in the public room (botany), British Museum, South Kensington. Names are most necessary to illustrations, and so is the amount of magnification of the spores. This Mr. Hay will also find has been carefully attended to in the original drawings, though not given by Dr. Cooke.

Mr. Hay's work has been most laborious, and he has exercised great care in the revision of the proofs. His "Fungus-Hunter's Guide" fairly reflects the plan of Dr. Cooke's "Handbook," but the popular names are doomed to obliteration. Many of the so called edible species are offensive and poisonous, at any rate in an uncooked state. Cooking may dissipate the highly acrid poison of some of the plants, but it is a mistake to recommend poisonous and nasty things for the table. If fungi are eaten without the most exact knowledge of the plants to be consumed, unpleasant results are certain to follow.

W. G. S.

Unstable.

ORCHIDS.*

THIS is a useful and cheap treatise by one who has had great experience of the subject on which he writes; consequently the information given is ample and varied, and such as cannot be obtained in a compact form anywhere else. The book is also published at a price which will bring it within the range of journeyman and apprentice gardeners, and to such it will be of great value. The present edition is also much more complete than the first, which was very favourably received. The chapter on Orchid culture seems such an essential part of any work dealing with these plants, that it seems singular any reference to culture was not included in the first edition. The chapter on Orchid life is very interesting, and well deserving of careful study; while those on Orchid flowers and Orchid mysteries, &c., are a necessary introduction to that on fertilisation. This last is a part of the work that young growers would do well to study. The number of ways in which Orchids may be successfully reared by cross-breeding is endless. The work itself is most interesting. Some people think it slow; this it undoubtedly is, but is there no pleasure in watching the development of the seed-pods; the scattering of the seeds, like dust in the sun-beams; and the appearance of the tiny seedlings, which gradually develop under the watchful eye of the cultivator to the stately plant, which will at last reward the patient labourer with its lovely flowers?

The historical part of Mr. Castle's book is very interesting to growers, containing, as it does, the prices paid for special plants at the various important sales.

The hints on Orchid culture are very valuable to beginners, and may be safely followed. Many valuable plants have been lost for want of knowledge on the part of the person in charge of them. I well remember, some twenty years ago, trying to grow *Cymbidium eburneum*, potted in peat and Sphagnum, exactly like *Cattleyas*, but the foliage was always sickly-looking, and died off brown at the tips, but when the treatment was altered, the plants potted in loam and treated as ditch plants (which they are), success was complete. There is, of course, a knowledge which can only be obtained by practical experience, but for information what to do, how to do it, and the right time to carry out the

* "Orchids: their Structure, History, and Culture." Illustrated. By Lewis Castle.

necessary details of the work, this unpretentious little volume may well find a place on every Orchid-lover's bookshelf. J. D.

ORCHIDACEOUS PLANTS.*

THIS monograph of the genus *Odontoglossum*, issued by Messrs. Veitch, is a welcome addition to our Orchid lore. The nomenclature adopted does not in all cases accord with that of Prof. Reichenbach, but the authors tell us they have followed the arrangement of Bentham and Hooker, as set forth in their "Genera Plantarum."

The plan of the work comprises a definition of the genus, species and varieties, together with cultural instructions, the descriptions being laid down in just that happy popular scientific form suitable to all readers without being overloaded with cumbersome technical terms, so that those who run may read and understand. The work is of royal 8vo size, comprises eighty pages, and contains some forty engravings of the leading types of the genus, which are faithful portraits of the species and varieties they are intended to represent. There is also added two coloured maps showing the districts where and the altitudes at which these *Odontoglossums* grow, so that it will be the cultivator's own fault if he does not make himself acquainted with the natural surroundings and requirements of the plants committed to his charge. The chapter on the geographical distribution of the genus *Odontoglossum* clearly proves that these are purely alpine plants, and is so interesting and so full of sound information, that we quote it for the benefit of our readers:—

The *Odontoglots* are confined to the mountain regions of Tropical America, from about lat. 15° S. to lat. 29° N. They are also restricted to particular mountain chains within these limits. Their southern limit is where the great Cordilleras of the Andes begin to draw closer together after enclosing the lofty plateau of Peru and Bolivia and where a change in the climatal conditions of the Andean region becomes perceptible. The most southern *Odontoglot* at present known is *O. compactum*, which occurs on a lofty ridge near Cuzco, called Las Tres Cruces. From Cuzco northwards as far as Chachapoyas the *Odontoglots* occur very sparingly, only three or four small-flowered species having yet been found; but at the last-named place they begin to appear at much smaller intervals. *O. myanthum*, *O. gracile*, and some other small-flowered species are reported from Loxa (Loja), and still nearer the equator the magnificent *O. Halli*, the beautiful *O. cirrhosum*, and *O. Edwardi* have their homes. North of the equator the Andes break into three distinct ranges, one, the eastern Cordillera, running in a north-easterly direction. It is on this range that the greater part of the most popular kinds occur, being most numerous and most abundant on that portion of it that lies between Bogota and Ocaña, and which may thence be regarded as an *Odontoglossum* centre. The middle range, called the central Cordillera, extends northwards and terminates at Cape Gallinas. Only a few species inhabit this range, but the valleys on both sides—that of the Magdalena on the east, and the Cauca on the west—are exceptionally rich in orchidaceous plants. Northwards of the central Cordillera the land again rises, and here the *Odontoglots* again appear, the first to occur being *O. chiniquense* and *O. curatifolium*.

The delicate *O. Krameri* and *O. Oerstedii* have their homes in Costa Rica, as also the more robust *O. Schlieperianum*. The genus is represented in Nicaragua by *O. rubescens*. The average elevation of the great wedge-like plateau of Mexico is not less than 7000 feet to 8000 feet. On these elevated lands the *Odontoglossums* at first occur sparingly, but gradually increase in numbers on advancing northwards towards Taxaca, where they appear to attain their greatest northern development, beyond which they again diminish in numbers till their northern limit is reached, at about the 20th parallel. Not far from this line is the southern limit of the Sierra Madre, where *O. maxillare* has its home, and eastwards from this is the Irapuan range, on which *O. maculatum* and *O. Cervantesi* were discovered; these are the most northern *Odontoglots* known. On the South American continent, from the southern limits of the genus to as far as the Isthmus, by far the greatest number of the *Odontoglots* occur within a zone whose vertical range rarely descends below 5000 feet, or ascends above 9000 feet. There are some species indeed, such as *O. densiflorum*, *O. compactum*, and a few other small-flowered species, which grow on rocks, or on the bare ground above the timber line to as high as 11,000 feet to 12,000 feet elevation.

The climate of this zone, by reason of its elevation, is decidedly temperate, the mean annual temperature being about 14° centigrade (57° Fahr.) for the higher portion, and 18° centigrade (65° Fahr.) for the lower, but the difference between the maximum and minimum temperature observed during the year is very great, the thermometer sometimes standing at 32° centigrade (90° Fahr.) and even higher when the sun is vertical, and descending to 4° centigrade (40° Fahr.) in the night. The atmosphere of this elevated region

* "A Manual of Orchidaceous Plants." Part I: *Odontoglossums*. James Veitch and Sons, Royal Exotic Nursery, King's Road, Chelsea.

is always at a very high degree of saturation, caused chiefly by the north-east trade wind by which the enormous evaporation from the Atlantic Ocean is constantly being drifted towards the Cordilleras, where it is arrested and condensed; the rainy season of parts of the *Odontoglossum* region is thus almost continuous throughout the year. At night when the temperature falls considerably below the mean, the vapour with which the atmosphere is always charged takes the form of a dense fog, which always leaves a copious deposit of dew before being dispersed by the rising day temperature. As a consequence of these climatal conditions the vegetation of the region is uninterrupted throughout the year; the whole belt is covered with a dense forest with occasional openings. The *Odontoglots* are found in the greatest abundance in those parts of the forest which skirt the occasional openings, and along the margins of the numerous mountain streams where there is freer access of light and air, and when it not infrequently happens that numbers of plants are found fully exposed to the direct rays of the sun. It is observed of these that their pseudo-bulbs are always smaller than those which are partially shaded; they also flower more freely, but the spikes are neither so long nor the flowers so large as those produced by plants in partially shaded situations; while those growing in more complete shade—on fallen trees or on the ground where there is always an excess of moisture—have large, fleshy pseudo-bulbs, rarely flower, suffer much by removal, and generally die during transmission to Europe.

North of the Isthmus, and especially within the Mexican territory, the local circumstances are somewhat different from those of New Granada, caused chiefly by the peculiar configuration of the land. Here the *Odontoglots* appear to be spread generally over those portions of the plateau wherever the conditions suitable to their well-being exist, as well as on the slopes of the central mountain ranges, and the various spurs that branch from them. The climatal conditions of the *Odontoglossum* region north of the Isthmus of Panama are also somewhat different from those of the *Odontoglossum* region of New Granada and Venezuela. Thus, in Guatemala, there is a wet and a dry season, the first commencing in December and ending in April, and the second lasting through the remainder of the year; there is thus a decidedly pronounced rest in the vegetation of the country, but on the higher grounds, where the *Odontoglots* have their home, there is always a high degree of saturation in the atmosphere, even in the dry season, caused by the moisture from the Atlantic and the lowlands being drifted thither by the trade wind, and which, during the nights in the early part of the year, takes the form of dense fogs. In Mexico the climatal conditions of the Tierra Fria are similar to those of the highlands of Guatemala, but the rainy season is of shorter duration; the temperature is remarkably uniform, the mean summer and winter temperature varying scarcely more than 6°–7° centigrade (10°–12° Fahr.). The precipitation caused by the trade winds attains its greatest strength on the eastern slopes of the mountains skirting the high central table land; here the rainy season lasts eight months of the year, and the temperature ranges between 12°–15° centigrade (55°–60° Fahr.). Throughout the whole of the *Odontoglossum* region there is never a perfect rest in the aerial currents; there is always a gentle breeze to be noted.

Those who attentively read the foregoing will find the whole secret of *Odontoglossum* culture clearly defined. The authors, in quoting temperatures, have used the centigrade scale in addition to that of Fahrenheit. The book is published at the nursery, but we believe it may be obtained through any bookseller. G.

KITCHEN GARDEN.

W. WILDSMITH.

STAKING PEAS.

"W." IN THE GARDEN (p. 518) seems to present us with a somewhat exaggerated estimate of the cost of staking Peas, especially as he appears to be a gardener on an estate where Pea sticks are plentiful. Were he resident in or around London, for instance, he would find that Pea-stick bundles are remarkably thin, just as they are high-priced, and that Pea-staking upon a considerable scale is very expensive. My own experience in those parts of the country where a really fat bundle of Hazel could be purchased for 6d. is that staking Peas pays, let the sort be what it may. As a rule, staked Peas give finer and cleaner pods, whilst the average crop is, as a rule, increased one third, and that, in an ordinary row of Peas, means a considerable quantity. Certainly, staked Peas need more space between the rows than those unstaked. Still, in gardens I think laid Peas are in more danger from birds than those that are staked. When the cost of sticks is excessive, even if that of labour is equal, then it is quite a matter for consideration whether the expense will be repaid. About London the cost of garden labour is some 20 per cent. greater than it is in rural districts; hence, the cost of staking Peas is greater. Still, the cost

of the sticks themselves is the primary consideration. Knowing what a handy man can do with a hook in pointing and trimming sticks, and how long it takes to fix a hundred or so, I think the labour expense is but a trifle as compared with the value to the Pea crop later; indeed, the cost of staking may easily be reimbursed by the greater facility found in gathering the pods. That many of our finest tall Peas develop too much barren haulm before they begin to pod is certain, and it is hard to make stakes to pay for the support of that. Still, all who have seen a good row of tall-staked Reading Giant, Ne Plus Ultra, or other lofty growing kinds must admit that if the root sustenance is liberal, the produce is wonderful. The longer the plants can be induced to grow and bloom, the longer are young pods being produced and the greater the work or profit obtained by staking. Mulehings of long manure or Grass may be given to staked Peas, but can hardly be given to laid Peas; indeed, too often, especially in wet seasons, these have to be turned to enable them to keep from rotting on the undersides. I write thus in defence of the use of sticks in Pea culture, although I have not used one with large quantities of Peas for some twenty years. Here I grow them in the open field, and when land is cheap and holding very good, paying crops of Peas may be had in that way without stakes, but in gardens, ground must be more economically employed. Here very dwarf kinds are sown in rows 2 feet apart, 3-foot to 4-foot kinds in rows 30 inches apart, and the tallest, such as Telegraph, Telephone, Duke of Albany, &c. 3 feet apart only. Plenty of air circulates, and birds give little trouble, because there is little shelter for them near. The crops, too, are, as a rule, excellent; in fact, as seen on the ground they often look remarkable, and I have tried again and again to induce market growers to grow some of the more favoured sorts for field culture, but they are afraid, because of the cost of the seed. It will be seen that I use on a given space of ground fully one-third more seed than would be used in a garden where Peas being staked grow tall. Gathering from laid Peas is at once more troublesome, and the harm done to the haulm is far greater than in the case of tall Peas, and for that reason the crop is rarely so continuous; in fact, after two good pickings it rarely pays to go over the haulm a third time. A. D.

LATE PEAS.

As a rule, late Peas are sown too early. When they blossom in August and pod in September the produce is neither plentiful nor tender. There is a general tendency to sow everything early. It is said, "get them in the ground, then they are done with," and that is true to a certain extent, but cultivators would do well to consider when they require the produce before sowing the seed. The middle of June is soon enough to sow the first of the early ones, and the end of the month is none too late to put in the latest batch. Such Peas will grow freely during July and August, flower in September, and the pods will be ready for gathering in October. There is nothing more disappointing in connection with late Peas than to have them ready for use before their proper time, but this is mainly the fault of sowing too soon. There are only three varieties of real value for late crops, namely, Latest of All, Omega, and Ne Plus Ultra. The first two are dwarf and compact; the last-mentioned is good in flavour, but it grows too tall. In many cases late Peas are sown in out-of-the-way places, the main quarters being mostly filled up at the time the crop is sown, and they are therefore consigned to the background. This often proves a mistake, as, although they may bear well in such places, the plants generally become attacked by sparrows, which are always destructive to Peas late in the autumn—in fact, many late crops are completely destroyed by the birds. For this reason alone we always try to sow our latest Peas in prominent places. Good culture throughout is necessary to secure a heavy and successional crop. The plants will fail long before August is over if sown in poor

shallow soil, and they will only succeed thoroughly in a deep rich staple. Trenches 12 inches in depth and 18 inches in width should be thrown out. Manure heavily in the bottom and sow the seed there. This will save them from the drought in July and August, and cause them to produce luxuriant and fertile growth. When this is secured there is no danger of failure in the late crop of Peas. J. MUIR.

Margum.

Late Broccoli.—We are now in the second week of June, and the variety of Broccoli known as Model is still in excellent condition with us. The heads are of medium size, excellent colour, and fine flavour. It is a first-rate May and June Broccoli, and I am much pleased that it was included amongst our vegetable seeds of 1886.—J. MUIR.

Over-cropping Cucumbers.—As a rule, all who grow Cucumbers try to have them in fruit as soon as possible, and make the plants bear a heavy crop. There is no harm attempting the first, but the last-mentioned plan is very injurious. When the fruits are hanging as close as they can be packed, the plants become exhausted and soon fail. All who wish to have Cucumbers in bearing condition throughout the whole season must avoid heavy cropping. It is always better to thin the fruits when they are small, or cut them before they have gained maturity, than to allow them to bear too much. We have had plants in fruit from May until November, and they proved most useful, but those which produced a heavy crop at first soon began to show signs of distress, and were never very satisfactory afterwards.—J. MUIR.

KITCHEN GARDEN NOTES.

PREPARING GROUND FOR PEAS.—Sprouting Broccoli and Cottagers' Kale, two of the hardiest as well as the most profitable winter greens, are only now being cleared off, having afforded us an unbroken supply of sprouts for many weeks past. The ground is required for late Peas, and we are therefore having it done as well as our stinted amount of labour at this busy season will admit of. A good coating of manure has been applied, and deep or double digging, *i.e.*, one spit deep and the next spit forked up, and manure spread over that, is the way the ground is being treated: and in addition to this manuring, the Peas will be sown in shallow trenches drawn out with hoes, a second dressing of manure being given by scattering in the trenches soot or some kind of artificial manure. Both late and early varieties of Peas will be sown as soon as the ground is ready.

THINNING OUT SEEDLINGS AND HOING.—A more favourable time for this work I have never known, and except Beet, Salsafy, and Scorzoner, which are scarcely ready, all others have been thinned, and at the present time we are busy hoeing amongst the various crops. There was necessarily a large amount of trampling over the ground during the thinning operations, so that extra deep hoeing is required to again lighten up the ground. As we only earth or ridge up Potatoes to prevent them coming through the soil, surface-hoeing between the rows to keep down weeds has to be done some three or four times during the season. The second hoeing is now being done, as is the case also with the plots of Jerusalem Artichokes, Sea Kale, and Rhubarb; in fact, with all crops not mulched.

PLANTING.—When the weather is showery and the ground available, no opportunity is lost of planting out small successional lots of Cauliflower, Coleworts, and Savoys. In our case, for want of ground, such small plantings cannot be succeeded by the main plantings of Broccoli, &c., till the crops of early Peas and Potatoes are exhausted, and therefore we take some pains to keep the plants in the best order, first by late sowing and on a north aspect, and next by keeping them thin on the ground, either by drawing out the weakest to make room for the others, or by pricking out. We have not time for the latter, and, except for early sowings in heat, the

former plan answers admirably for all except Brussels Sprouts; these should always be transplanted before the final planting.

MARROWS, CUCUMBERS, CHILLIES AND TOMATOES.—The two first are growing freely, and once a week require attention as regards pinching, training out, pegging down, and weeding. At no time do we allow the growths to become crowded, a state that for the most part is the precursor of mildew and of green or black fly, which, if once they get the upper hand, failure is almost certain. Methodical or regular weekly attention is the best way of ensuring freedom from such evils. We add fresh soil to each, according as the presence of surface roots indicates such a requirement. Abundance of water and overhead syringing in dry weather are essential to a vigorous growth. Chillies we have only just planted out on mild hotbeds composed mainly of the Grass from the mowings of lawns. The soil is a mixture of loam and vegetable mould in about equal proportions, and is made rather firm, which, I fancy, conduces to fruitfulness rather than to an undue amount of wood growth. Tomatoes on walls and in the open are already in flower and the plants strong, being in 5-inch pots when first turned out. Those on walls are well secured, and those on the open border supported with stout stakes, one to each plant, the plants being trained upright, cordon fashion, only one stem being allowed to a plant. The consequence is that we get an abundance of side lateral growths that fruit much more freely than sucker stems from the base of the plants. The ground can scarcely be too firm, and our plan of mulching all the ground about them with long litter is a help to the plants. Tomatoes that are fruiting in pots we have now turned out of the houses, and arranged them in warm sheltered nooks about the houses, where they will continue fruiting the most part of the summer, if given rich top-dressings or waterings of liquid manure, which they ought to have at least twice a week.

GENERAL WORK. Hoeing, staking Peas, watering in dry weather Celery and all recently planted Cauliflowers, Coleworts, &c. To mulch, as litter becomes available, Peas and Runner Beans, and, in fact, any crop that is likely to benefit from the practice. To make other sowings of Lettuce, Endive, Radish, and Spinach, and in showery weather sprinkle Onions with soot and Turnips with finely sifted wood ashes, which is an excellent antidote against the ravages of Turnip fly. W. W.

Insecticides and their use.—Pyrethrum when fresh and pure kills by contact many soft-bodied larvae and other insects. It may be applied either dry or in solution—a tablespoonful to a gallon of water. Pyrethrum consists of the dry powdered flowers of three varieties of Pyrethrum, and loses its insecticidal properties after prolonged exposure to air. Hence the necessity of obtaining the fresh article—often a difficult thing to do, because dealers palm off their last year's supply as fresh, rather than throw it away. Pyrethrum is excellent for killing Cabbage worms, Cherry and Rose slugs, Currant worms, and other pests. Hellebore—a substance composed of the powdered root of white Hellebore—kills both by contact with the skin of insects and also by being eaten. It is especially valuable for destroying Currant worms and similar insects. It may be applied as a simple powder, or mixed with water, one ounce to two gallons, and sprayed on. Kerosene, like Pyrethrum, has only recently been successfully used for this purpose, but promises to occupy an important place in the future of economic entomology. Probably the soap emulsion, prepared according to the following directions, will prove the simplest and most practical method of using that has as yet been recommended. The formula is: kerosene, 2 gallons, 67 per cent; soap (common) or whale oil, half a pound, and water, half a gallon, 33 per cent. Heat the solution of soap and add it, boiling hot, to the kerosene. Churn the mixture by means of force pump and spray nozzle for five or ten minutes. The emulsion, if perfect, forms a cream, which thickens on cooling, and should adhere without oiliness to the surface of glass. Dilute

before using one part of the emulsion to nine of cold water. Tobacco as an insecticide is good, but as it cannot be purchased in a prepared form, it is more difficult of application.—C. M. WEED, in *Orchard and Garden*.

TREES AND SHRUBS.

W. GOLDRING.

THE SNOWDROP TREE AT HAMPSTEAD.

WE were pleased to see two young Snowdrop trees laden with blossoms in Sir Spencer Wells' garden at Hampstead on the 18th ult. It seems curious that a little tree so beautiful should only meet with the fate of a botanical curiosity. Its name is happily characteristic; the flowers come in plenty; the distant effect of the tree is very pretty and distinct; it is quite hardy. These young trees were planted by Sir Spencer Wells only a few years ago; now every twig carries flowers. We have never seen the Snowdrop tree a large one. With us, it is a true lawn or pleasure-ground tree; but we have seen it in old age with a very picturesque habit, as at Syon House a few years ago. The old tree we saw there is probably now dead. In trees, as in landscape pictures, merit is not always the way to popularity. We see people gloating over pictures rich in effective doses of strong colour, but embodied falsehoods as regards the ways of sun and light. We see diseased variegated trees popular, while this tree of rare beauty and refinement is seldom grown. W. R.

Cupressus nutkaensis compacta.—The Nootka Sound Cypress is well known as among the most ornamental of our hardy Conifers, and quite recently its merits were dwelt upon in THE GARDEN. I did not, however, see any mention of this variety, which is characterised by a dwarfer and more compact habit than the type, and forms a very ornamental member of the smaller growing Coniferae. Where the larger form would be inadmissible this is a very good substitute. It can also be kept for a long time in good health when treated as a pot plant, and on that account it is well suited for furnishing balconies and such spots.—T.

Skimmia fragrans in flower.—The best known Skimmia is *S. japonica*, and that is chiefly grown for its ornamental berries, but the species under notice forms just now an attractive flowering shrub, for each twig is terminated by a cluster of whitish blossoms. Like the other members of the genus, it succeeds best where the soil is fairly moist and not too fully exposed to the sun, but at the same time where quite clear of overhanging trees. Irrespective of flowers or fruit, it is a neat evergreen shrub, and one that will succeed fairly well even in smoky towns, for I have seen it preserve its original freshness for years in such a spot where little else would grow. Cuttings of this Skimmia may be taken at almost any season of the year if kept in a close frame till rooted. If put in now they will strike in about six weeks.—T.

SHORT NOTES.—TREES AND SHRUBS.

Blue Gum tree (Eucalyptus globulus).—We have received flowers from Mr. Christian, Chislehurst, who has a specimen in a conservatory bearing hundreds of flowers. The colour is a creamy white, and the fragrance delicate. This very rarely blooms in this country.

Snowy white flowered Bramble (Rubus deliciosus) is well named, the flowers having a delicate and delicious fragrance. They are pure white and of bold character, showing up well on a wall, in which way it is grown at Kew. We are not over-rich in spring-flowering wall trees, so those who require a choice addition to their collection might add this with advantage.—C.

The double Kerria.—This plant is well adapted for growing against a wall. The bright yellow flowers are borne profusely and contrast effectively with the fro-h green colour of the young leaves. Some of the cottages in Sussex are perfect pictures, although alone embellished with this shrub. An excellent combination was seen a short time back near

Three Bridges. The cottage wall was covered with Ivy and the Kerria loosely tied up in front, the sombre hue of the Ivy imparting an additional charm.—A. HERRINGTON.

Laburnum hedges are not commonly seen, but they have their uses. At this season, when loaded with flowers, they are delightful, and the elegant light green leafage is beautiful from early spring until late autumn, but especially so in the first-mentioned season. In only two or three instances have we noted the Laburnum grown in this form.—T. W.

THE SHRUBBY TREFOIL.

(*PTOLEA TRIFOLIATA*.)

THIS is one of those old-fashioned North American trees that were introduced to England during the early part of the last century by Bishop Compton, when he lived at Fulham Palace, as the Bishop of London does now. From 1675 to 1713 Bishop Compton was continually introducing foreign trees to this country, chiefly from North America. He made his garden at Fulham quite a nursery for trees and shrubs, rearing seedlings and propagating young plants himself. He not only devoted all his leisure time to his favourite tree, but spent large sums of money in introducing new kinds. The Ptelea was one of his special favourites, and history tells of the trouble he took to import seeds, how he tended the seedlings, and how, after all, he lost all his plants in a few years. The date London gives of the first introduction of the Ptelea is 1704, and after it was lost, Catesby, a celebrated traveller in North America, was the means of reintroducing it from Carolina about the year 1724, so that it has been in English gardens for upwards of a hundred and sixty years.

The tree is a handsome and uncommon-looking tree, small in size, the average height of the largest trees being only about 20 feet, and this height is attained only when the tree is stem-pruned. If unpruned, its style of growth is more that of a shrub than a tree, and it makes a large spreading head like an Elder. The large trifoliate leaves make it distinct from all others of a similar character. The flowers are small, greenish white, and inconspicuous, but the fruits or seed vessels, as they are like those of an Elm, but much larger, give the tree quite a remarkable aspect in late summer. The Ptelea thrives best in a damp and rather shady spot, though it will grow in any soil or situation. It looks better rising out of a group than isolated on a lawn, as it is apt to become bare at the base. A far more effective plant than the original is a golden-leaved variety (*aurea*), which is one of the finest golden-leaved trees we have, as it preserves its colour throughout the season, and is so hardy that the leaves seldom become disfigured by wind or cold in spring. The Ptelea is a tolerably common tree in nurseries, being easily propagated by seeds or cuttings.—W. G.

The Spanish Furze (*Genista hispanica*).—This is a remarkably pretty low-growing shrub, forming a dense mass a foot or so high, which at this season is completely covered with rich golden blossoms. It is eminently fitted for planting on rockwork, as, associated with other and perhaps larger growing shrubs, it is liable to be overshadowed; whereas when nestling on a ledge of rockwork, or forming a golden cushion at the base thereof, its beauties are then displayed to the best advantage. In dry soils the roots run deep, and on that account it will resist drought better than many other shrubs. Cuttings of the half ripened shoots put in a frame strike root without difficulty, or an established plant can often be divided with sufficient roots to each portion.—H. P.

Early flowering shrubs.—*Prunus Bissardi* is not so striking now as some would have us believe. It is not, in my opinion, so good at the present time as the purple Beech. In the autumn it is very

beautiful; the flowers are of a dirty white or washed-out pink colour. The common Service Tree (*Pyrus Sorbus*) is just now very telling, and its flowers are strongly scented. *P. M. Dovastoni* has been very pretty; it is very desirable owing to its early-flowering character. *Spiraea Thunbergi* is, I consider, one of the most graceful and ornamental of all shrubs; it has been flowering for a long time in a secluded spot amongst a lot of Evergreens. *Cerasus communis* is very early, and standard trees look well peering above low-growing Lilacs. Thorns and Chestnuts are all in flower now, and present a charming appearance. Maples are looking very fine, and it is somewhat strange that they are not more grown.—W. A. Cook.

ORCHIDS.

W. H. GOWER.

THE BLUE VANDA.

(*V. CÆRULEA*.)

THIS beautiful species is a native of Khasya, where it grows upon the branches of forest trees at from 3000 feet to 5000 feet elevation.

Vanda cœrulea.

In the winter hoar-frost is said to occur on the ground below these Vandas, whilst in the flowering season the temperature runs up to 80°. In cultivation this has always been a difficult plant to manage, the chances of maintaining it in health for any length of time being very uncertain. It certainly enjoys a fair amount of heat during the summer, but in winter it should be removed into the Odontoglossum house. At all seasons the plant should have an abundance of air and moisture, and very little Moss or peat should be used about its roots. The leaves of the plant are small compared with the size of its flowers; these are arranged in a two-ranked manner, whilst the spikes of bloom are more or less erect, oftentimes becoming drooping by the weight of their numerous flowers. These are, in

the sepals and petals, of a lovely shade of lavender-blue, tessellated with lines of a darker hue; lip small, deep violet. Its colour is rare amongst Orchids, and when grown and flowered in the manner shown in our illustration, it is an object of rare beauty.

FLOWERING ORCHIDS AT SOUTHAMPTON.

THE collection of these plants at Wilton House, Southampton, the residence of Mr. H. J. Buchan, is a very rich one, being extensive in number of plants, and also in the great number of species and varieties; just now about 150 distinct kinds are blooming, and over double that number of plants are contributing to the display. Amongst the leading features is the grand show of *Odontoglossum vexillarium*; twenty-six plants of this species are bearing nearly 800 flowers. Mr. Osborne grows these plants on the north side of an intermediate house, in which position, he says, they get just the heat and shade they enjoy, and are not subject to attacks from thrips, as they frequently are when grown in strong light. This same treatment also suits *O. hastilabium* admirably, judging by the numerous strong spikes, each bearing upwards of fifty flowers. In the coolest house, *Odontoglossums* are blooming most profusely, notable being *O. Halli*, with spikes 5 feet long, laden with flowers; *O. leucoglossum* and the distinct and beautiful *O. polyxanthum*; as also *O. naevium majus*, which seems to be extremely rare in its native country, as none of the numerous collectors find it. Other noteworthy kinds are the bluish-purple *O. Edwardi*, the creamy *O. ramosissimum*, whilst of *O. Alexandra*, *O. Pescatorei*, *O. odoratum*, and *O. roseum*, the show is extremely beautiful and varied, more than three dozen members of this genus now contributing to the display. Associated with the above, but in the very coolest part of the house, is a large collection of *Masdevallias*, the chief kinds being *M. Harryana* in great variety, the curious *M. Crossi* and *Sehlmi*, *M. ignea*, *M. Denisoniana*, the fine form of *M. Veitchi* called *grandiflora*, *M. rosea*, the hybrid *M. Chelsoni* and numerous others. The *Ocidiids* are also well grown and flowered. Amongst them we noted fine examples of *O. Marshallianum*, some of them grand varieties; the old, but beautiful, *O. sessile* and *ampliatum majus*, *leucochilum*, *stelligerum*, and many other kinds too numerous to mention. *Cattleyas* are extremely gay, the most notable being *amethystoglossa*, *Schilleriana*, *Aclandiae*, and *superba splendens*. *C. Skinneri* has been very fine, but is fast going past, to be succeeded by numerous forms of *Mendeli* and *Mossii*. The rare *C. Sanderiana* is now also displaying its large and gorgeous flowers. Two varieties of this plant are now flowering, and may be distinguished by their growth; one form has short, thick, clavate pseudo-bulbs, whilst those of the other are more slender and a foot long. The dwarf form produces the richest coloured and largest flowers. There are here also some wonderfully fine varieties of *C. Warneri*, *Lælia elegans*, and *L.*

purp. ata. The *Lady's Slippers* (*Cypripediums*) come in for a considerable amount of attention; the beautiful *C. Sedeni candidulum* was raised by Mr. Osborne at about the same time as it appeared with the Messrs. Veitch, of Chelsea, and from the same parents. The most conspicuous kinds now flowering are the long-tailed *C. caudatum*, bearing thirty flowers—it is said to thrive best in small pots; the yellow-flowered *C. Druryi*; the beautiful *C. lavigatum*—perhaps more correctly called *C. philippinense*—*ciliolare*, *Lawrenceanum*, *superbians*, and others. Turning to the purely Fast Indian plants, *Dendrobiums* are well represented; amongst the black-haired kinds, *D. Jamesianum* and *eburneum* are blooming profusely, so also is the pure white *D. Dearei*, which continues in full perfection for so many weeks. Of the more or less knotted-stemmed kinds, *D. crassinode*, *Parishi*, *Ben-*

sonia, and tortile roseum are very striking, as also are *D. suavissimum* and *densiflorum*. These plants are grown in strong light, but shaded from the hottest of the sun's rays, and are thoroughly rested by reduction of the temperature in winter. Vandas are represented by numerous forms of *suavis*, tricolor, and the beautiful variety of *teres* called Andersoni. The Moth Orchids now flowering are *Phalanopsis amabilis* and its rosy companion *P. Sanderiana*; whilst *P. Schilleriana*, which is usually looked for at the beginning of the year, still continues in its pristine beauty. Other distichous-leaved kinds are several forms of *Acrides* and *Saccolabium*, *A. Warneri* and *A. affine* being particularly good. *Oncidium lanceum* is just producing its spikes. These plants are suspended close to the glass, where they are exposed to the full light, the atmosphere being kept well charged with moisture. Under these conditions the plants thrive well, and the leaves are not disfigured by that nasty black, cankerous spot, which is too common a feature upon this species.

Green flowers are not usually very attractive or desirable, but exception must be made to three kinds now flowering with Mr. Bachan, viz., *Cyclogyne Parishii* and *pandurata*, and *Epidendrum prismatocarpum*; the two former, East Indian plants with black and green flowers, are grown in the hottest house; the latter, although a native of Mexico, also enjoys the same strong heat. It has erect spikes of green, black, and pink blooms. The terrestrial *Calanthes* are represented by such kinds as *C. veratrifolia* and *masuca*, some plants of which are bearing a dozen or more spikes. These have been potted in a compost consisting of turfy loam, cow manure, some nodules of charcoal, and a little sand. After the pots are tolerably well filled with roots a little Clay's Fertiliser is mixed with the water, and administered until growth is completed.

W. H. G.

Dendrobium speciosum.—If it is not generally known, the information cannot be too widely diffused that the above named plant can be made to bloom freely and regularly with very simple treatment. After the young growths are matured, the plants should be gradually hardened off, and then set outdoors in the full sun during the summer months, and during this time water should be entirely withheld. After removal indoors in autumn, no water should be given until its spikes begin to swell, when more heat and moisture will be required to develop its flowers. *D. Hillianum* may also be treated in the same manner with the like beneficial results, but on account of its pseudo-bulbs being more slender, it cannot so well withstand so severe a drying, and therefore care is necessary to avoid shrivelling. I have for several years treated both plants in the above manner and have always been rewarded with a fine display of bloom.—W. H. G.

Cattleya gigas.—A fine form of this superb species is now flowering with Mr. Penfold at Beldington House. The plant is grown in an ordinary intermediate house, and during winter has been rested in the coolest end of a warm greenhouse; it has two spikes bearing ten blooms, the individual flowers measuring upwards of 9 inches across, sepals and petals large and broad, rosy lilac in colour; lip bold, rich violet-purple, with a large yellow eye-like blotch on each side of the throat. Several plants of this species are also very fine at Selborne, the residence of Mr. Southgate; the plants here are also kept cool during the winter months; they vary much in habit, some producing very stout and long pseudo-bulbs with broad foliage, and others comparatively slender and weak ones. Mr. Salter says he has invariably found that the bold and robust growers are the shyest ones to bloom. This experience is substantiated by the fine form now flowering with Mr. Penfold, whose plant is but moderately robust.—W. H. G.

SHORT NOTES.—ORCHIDS.

Oncidium lamelligerum.—This somewhat rare *Oncid* is now flowering freely in Mr. James's nursery at Norwood. It is a supposed natural hybrid between *O. macranthum* and *O. serratum*; in colour the flowers resemble the former and

in shape the latter kind. The habit of the plant is very robust, and it succeeds under the coolest treatment.—W. H. G.

Odontoglossum Regelianum.—This interesting new species is now flowering with Mr. Sander at St. Albans. It appears to have some affinity to *O. constrictum*, and when fully established in cultivation will doubtless prove a welcome addition to the now numerous class of cool house orchids. The sepals and petals are yellow, streaked and blotched with reddish brown; lip white in front, spotted in the centre with purple, and stained at the base and on the crest with a somewhat deeper shade of the same colour.—W. H. G.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL.

JUNE 11.

THERE were many interesting exhibits at South Kensington on Tuesday last; but the display, although larger than at the previous meeting, was small considering the season. Pyrethrums and Peonies comprised the most important hardy flowers, and Orchids were represented principally by a group sent by Mr. F. G. Tautz, Studley House, Shepherd's Bush.

First-class certificates were awarded as follows:—

PYRETHRUM MARGARET MOORE.—A large handsome flower, over 3 inches across, the florets broad, and of a delightful shade of pink. Shown by Mr. T. S. Ware.

IXIOLIRION TATARICUM.—A hardy bulbous plant from Turkestan; excellent for the border or rockery. It blooms freely, the flowers exhibiting two shades of purple. From Mr. T. S. Ware.

HEMEROCALLIS MIDDENDORFIANA.—A distinct Day Lily, and far superior to the old *H. flava*. The flowers are of large size, and bright yellow in colour. It will be a valuable acquisition to our hardy early summer-flowering plants. Exhibited by Mr. T. S. Ware.

DOUBLE PYRETHRUMS.—Magician, a distinct variety, the flowers neat and finely quilled, colour pink tipped with yellow; Florentine, a somewhat loose flower, large, white, with faint tinge of pink; Aphrodite, pure white, beautifully quilled, but wanting in form; Figaro, a neat flower, the colour bright crimson, tipped with white. Exhibited by Messrs. Kelway and Son.

MASDEVALLIA LUTEA OULATA.—A distinct variety of *M. Harryana*; the neatly shaped flowers of medium size, and an intense shade of scarlet, the yellow throat affording a bright contrast. Exhibited by Mr. F. G. Tautz.

CYCLOGYNE DAYANA.—A fine specimen, bearing four pendulous racemes, each upwards of 3 feet in length, and each bearing about two dozen flowers. The sepals and petals are light brown in colour; the narrow tubular lip white, with conspicuous dark brown stripes on the lateral lobes, the margin distinctly ridged. Shown by Mr. Ballantine, gardener to Baron Schroeder.

ODONTOGLOSSUM VEXILLARIUM RADIATUM.—This bears freely comparatively small flowers; the sepals and petals are rich pink, the blood-crimson stained base of the lip giving the flower an effective appearance. It is at once distinct and pleasing. Exhibited by Baron Schroeder.

EREMULUS ROBUSTUS VAR.—A white-flowered form, the spike, as shown, measuring fully 3 feet, and, judging from its appearance, would develop to fully 10 feet, as is the case in the type. The flowers are white, and more densely produced than in the parent. Shown by Mr. E. G. Loder, Floore, Weedon.

PELARGONIUM DUKE OF CLARENCE.—A show variety; the flowers large and of good form; the lower sepals scarlet, the upper suffused with velvety purple; the trusses of bloom are, however, rather small. From Mr. E. B. Foster, Clewer Manor, Windsor.

There were several Orchids shown, the chief exhibit being the group from Mr. Tautz, which included, amongst others, the following: *Dendrobium microglossum*, the flowers small, pink, and

freely produced; *D. Veitchianum*, the colour yellowish green, the lip large and much dilated; *Laelia purpurata alba*, pure white save the lip, which is blotched with velvety crimson-purple; *Cypripedium superelliere ornatum*, a large flower of light colouring; *C. Lawrenceanum atro-rubrum*, a striking variety, the lip chocolate-brown, the dorsal sepal fully 2 inches in diameter, suffused with rich crimson at the base and striped with the same hue; the whole flower has a glistening appearance, which greatly adds to its beauty; *C. Lawrenceanum grandiflorum*, a large-flowered form of the type; *C. caudatum giganteum*, a bolder flower than the old *caudatum*; and *Acrides Houlettiana*, a beautiful species from Cochin China, the flowers large, sepals and petals pale yellow tipped with light magenta, the lip white, blotched with magenta. A silver-gilt Banksian medal was awarded. Mr. F. Wigan, Clare Lawn, East Sheen, sent a large form of *Phalenopsis grandiflora*, the flowers of great width and substance; *Cattleya gigas Sanderiana*, a fine variety with a very highly coloured lip; and *C. Mendeli limbata*, very chaste, white lightly tinged with pink, the front of lip bright rosy crimson. A good specimen of *Cattleya Warneri* and a showy variety of *C. Mossie* came from Mr. E. H. Whitwell, Barton Hall, Darlington; there are now so many forms of *C. Mossie* that unless the variety is of exceptional merit it is useless to give it a distinctive name. *Cypripedium Cheltonia* was shown by Messrs. Heath and Son, Exotic Nursery, Cheltenham. Mr. R. B. White, Ardarauch, Gareloch Head, exhibited *Dendrobium polyphlebium*, a hybrid between *D. primum* and *D. Parishii*; the flowers are of similar shape to those of the former; the colour rosy pink. Baron Schroeder exhibited besides the two Orchids certificated, *Odontoglossum vexillarium vestita*, a variety with flowers almost pure white. *Odontoglossum crispum*, Blair's variety, sent by Mr. Blair, gardener to the Duke of Sutherland, Trentham, Stoke-upon-Trent, is a distinct and well-coloured form, the sepals and petals white, blotched with rich brown and pale lilac. From the collection of Mr. Day, High Cross, Tottenham, came a variety of *O. crispum* named *Wolstenholmia*; the plant bore a long raceme, but the flowers lack brightness, the washy lilac blotches on the sepals and petals giving them a dull appearance. A variety of *O. crispum* called *albanense* was shown by Messrs. Sander and Co., St. Albans, the flowers large, blotched and barred with light brown on a white ground; the same firm also exhibited another form of *crispum* named *Schroederi*; it is very distinct, the shell-like sepals and petals white, of a rich bright crimson colour. *Cattleya Mossie Pectersi*, sent by M. Pecters, Brussels, is a good form, but the plant was in bad condition; the flower is of bold character, and rich pink colour. The Duke of Marlborough, Blenheim, contributed *Cattleya Mendeli picturata* and *C. M. limbata*, both good varieties; the former rose-coloured, with the tubular lip white, blotched light crimson; the other rich pink, save the lip, which is vivid crimson.

Messrs. Veitch and Sons, Chelsea, exhibited *Anthurium Bakeri*, the spathe small and of a green colour, the spadix much developed, the berries large and highly coloured; an interesting plant. Dr. Wallace, Colchester, sent *Blandfordia flammula aurea*, flowers golden yellow. It is probably owing to their difficult cultivation and shy-flowering character that *Blandfordias* are not more often seen. *Leschenaultia biloba major*, a greenhouse plant too seldom seen, came from Mr. W. Balehin, Hassocks, the flowers of a brilliant blue and most effective when seen in a mass; a cultural commendation was awarded.

Hardy flowers made an interesting feature. The group from Mr. T. S. Ware comprised many choice plants. Amongst Irises the most noteworthy were *I. Victorine*, rich purple falls, whitish standards; *I. pallida dalmatica*, lovely lilac colour; and *I. Gracchus*, crimson striped falls and canary-yellow standards; very pleasing. Of the Day Lilies, *Hemeroallis flava grandiflora*, a large form of the type; *H. Dumortieri*, orange-yellow, distinct shade; and *H. Middendorfianna*, previously described, were the

best. There were also examples of the interesting *Lewisia rediviva*, the flowers white and borne on short stems; *Panicratium illyricum*, white, small, and delicately fragrant; and the yellow *Calochortus pulchellus*, very pretty. A silver Banksian medal was awarded. Messrs. Barr and Son, Covent Garden, also had a large group, consisting principally of Peonies, Irises, and Pyrethrums, some of the varieties remarkably effective. A silver Banksian medal was awarded. Mr. Gordon, Twickenham, sent a collection of Peonies; the flowers had, however, suffered considerably in transit. Messrs. Kelway and Son, Langport, Somerset, were awarded a bronze Banksian medal for several boxes of single and double Pyrethrums, the varieties showing to what a high state of perfection these flowers have been brought; Milton, deep crimson, was one of the most showy of the doubles. Messrs. J. Carter & Co., High Holborn, sent well-grown plants of the Edelweiss and the pretty *Stenogastera concinna*; for the former they were awarded a cultural commendation.

Mr. R. Dean, Ealing, contributed *Aquilegias*, the deep blue-flowered *Phacelia campanularia*, a remarkably showy annual, and *Chrysanthemum multicaule*, single yellow flowers, very pretty. Seedling Carnations were sent by Mr. R. Spinks, Victoria Road, Hoxley; and a choice variety of Pansy blooms by Mr. Henry Eckford, gardener to Dr. Sankey, Baschurch, Salop. *Anemone King of the Scarlets*, a double scarlet variety, was shown by Mr. R. Gilbert, Dyke, Bourne, Lincolnshire.

Messrs. H. Collyer and Co., Tunbridge Wells, exhibited a dark-leaved form of the popular *Ampelopsis Veitchii* named *purpurea*; if it proves as free-growing as the type, it will be a valuable acquisition. Messrs. Paul and Son, The Old Nurseries, Cheshunt, sent *Rhododendron Fortunei*, Mrs. Chas. Butler, a pleasing variety, the flowers large, delicate pink, sweetly scented. Mr. E. G. Loder, Floore, Weedon, showed well-developed flowers of the striking *Cypripedium macranthum* and *C. Calceolus major*, a large-flowered form of our common Lady's Slipper. From Mr. G. F. Wilson, Heatherbank, Weybridge, came an unnamed yellow Primrose, probably a hybrid between *P. japonica* and *P. involucrata*, resembling the former in foliage, while the flowers remind one of the last-mentioned. A few plants of interest were sent from the Royal Gardens, Kew. They comprised *Salvia scapiformis*, a small plant bearing a profusion of light lilac flowers on spikes about 6 inches in length; it comes from Hong Kong; *Oxalis brasiliensis*, a free-flowering Brazilian Wood Sorrel, the flowers bright rosy pink; very useful for the cool house; *Streptocarpus Dunalii*, a native of the Transvaal; flowers reddish, freely produced; the delicate violet-coloured *Wahlenbergia graminifolia*; and the Golden Drop (*Onosma taurica*).

Fruit committee.—The subjects brought before the committee were few in number. Mr. G. Norman, The Gardens, Hatfield House, Herts, showed Melon Dempsey's Favourite and Sir Charles Napier Strawberry; the fruits of the last mentioned were remarkably fine. There was little competition for the prizes offered by Messrs. Suttons & Sons, Reading, for the best brace of Melons: Mr. T. Lockie, Oakley Court Gardens, Windsor, was first, and Mr. H. W. Ward, Longford Castle Gardens, Salisbury, third.

The Gardeners' Orphan Fund.—The efforts of the promoters of this fund are being vigorously applied to perfecting a scheme to be laid before the horticultural community. Some three weeks ago the provisional committee appointed a sub-committee to draw up rules and regulations under which the fund will be administered; and this committee met on two occasions at the Royal Horticultural Society's Gardens at Chiswick, and framed the same, which were submitted to a meeting of the provisional committee on Tuesday last, held in the conservatory at South Kensington, and unanimously approved. It is intended to convene a public meeting of horticulturists and those interested in the fund at South Kensington, on July 12, when the provisional committee will make a report, and the fund will be established. Due notice will

be given of this meeting. Messrs. James Veitch and Sons have generously promised the sum of £100 to the fund, and Baron Schroeder has, through Mr. H. J. Veitch, promised to become a supporter of the same. So much support has been received, that the success of the movement is now placed beyond doubt, and a list of supporters will appear in due course.

ROYAL BOTANIC SOCIETY'S EXHIBITION.

JUNE 15.

THE second summer show of this society was, on the whole, very fine and favoured with brilliant summer weather. The exhibition was of the usual character, stove and greenhouse plants forming an important feature, though we remark with pleasure that the huge stilted trained specimens have certainly had their day. Hardy flowers were plentiful; also Orchids, and there were many artistically arranged groups in the miscellaneous class.

STOVE AND GREENHOUSE PLANTS IN BLOOM.—Mr. J. Cypher, of Cheltenham, was first in the open class for twelve, the following being well grown and densely flowered: *Erica Cavendishii*, *Clerodendron Balfourii*, *Ixora Pilgrimi*, *Anthurium Scherzerianum*, and *Bougainvillea glabra*; Mr. D. Donald, gardener to Mr. J. G. Barclay, Leyton, second, having a fine specimen of *Azalea Flower of Spring*. Mr. Henry James, Castle Nursery, Norwood, was well to the front in the class for six, one of the best plants being a well-flowered *Azalea Barclayana*; *Anthurium Wardianum* was also in good condition. There was a decided falling off in the amateur classes; in some instances the plants were very indifferently grown. Mr. D. Donald occupied the first place, but the exhibits call for no particular comment.

ORCHIDS were the brightest feature of the show. There were five classes allotted them, Mr. J. Douglas, gardener to Mr. F. Whitbourn, Great Gearys, Ilford, occupying the first place for twelve; the plants exceptionally well grown and flowered, especially *Laelia purpurata* and *Cypripedium Lawrenceanum*; Mr. Hill, gardener to Mr. H. Little, The Barons, Twickenham, a good second; *Cattleya labiata Warneri* and *Cypripedium barbatum grandiflorum* were noteworthy. In the nurserymen's class for twelve, Mr. J. Cypher was first with capital plants; *Cypripedium barbatum* and *Anguloa Clowesi* were especially good; Mr. Henry James second, his *Cattleya Mossiae* and *Epidendrum vitellinum majus* being worthy of mention. The last-mentioned exhibitor was also first in the class for twelve single specimens; the plants were moderately good, including a well-grown *Vanda suavis*. In the amateurs' class for twelve specimens, Mr. J. Douglas was to the fore, his group including a fine specimen of *Cymbidium Lowianum* bearing several spikes of its pale greenish yellow flowers; *Laelia purpurata* was of high merit, also *Saccolabium guttatum*; Mr. F. J. Hill, a close second, the specimens well flowered.

ROSES were in poor condition, the dry weather of the past week or so having affected them considerably. Six classes were devoted to these, the principal one for twenty-four, in which Mr. J. G. Trauter was the only exhibitor; for twelve varieties, Mr. J. Hollingsworth, Turkey Court, Maidstone, occupied the post of honour; and this exhibitor was also successful in the class for six distinct. Mr. A. Gibson, gardener to Mr. F. F. Burnaby-Atkins, Halstead Place, Sevenoaks, exhibited fair flowers of *Niphetos* in the class for twelve trusses, any one colour. For twelve trusses, yellow, Mr. A. Gibson came first with *Maréchal Niel*.

PELARGONIUMS are generally seen to advantage at the Botanic shows, and the present occasion proved no exception to the rule, though the competition was less severe than in the days of yore. The fancy section was well represented. In the nurserymen's class for six Mr. C. Turner, Royal Nurseries, Slough, was deservedly placed first, the specimens densely flowered, especially *Ellen Beck*, *The Shah*, *Princess Teck*, and *East Lynn*. In the corresponding class for amateurs, Mr. D. Phillips, Langley Bloom, Slough, was first. In the first prize lot *Delicatum* and *Princess Teck* were good, and in the latter *Roi des Fantasies* was about the best. In the

other class for *Pelargoniums* the order of things was reversed, Mr. J. Hill coming first and Mr. D. Phillips second; the plants of the former were well grown, especially *Mdme. Favart*, light red; and *Ruth Little*, rosy pink upper petals, the lower blotched with velvety maroon. Mr. C. Turner was first for six show *Pelargoniums*, *Amethyst*, *Gold Mine*, and *Comtesse de Choiseul*, well flowered. The zonal varieties were very good, Mr. H. Eason, gardener to Mr. Noakes, Hope Cottage, Highgate, staging well-flowered examples. Amongst the most effective varieties were *Nelly Thomas*, scarlet; *Constance*, pink; and *Zelia*, showy red. He was closely followed by Mr. Hill, who had plants of unequal size, *Atala* and Mrs. Gordon being the finest, the colour dazzling scarlet.

TUBEROUS BEGONIAS were exhibited in fine condition by Messrs. J. Laing, Forest Hill, who were a long way ahead in the class for twelve, the plants medium-sized, and full of flower; *Queen Victoria*, scarlet, hardy; *Chesterfield*, fine pink; *Ball of Fire*, well named, were the most conspicuous. There are few more effective plants when well grown than tuberous *Begonias*, and the rapidity with which they have been developed is marvellous.

CUT FLOWERS.—These were fresh and good, especially the *Iris*. In the class for a collection of the latter, Messrs. Collins Brothers and Gabriel headed the prize list; the flowers were well grown and nicely put up, Mr. T. S. Ware followed closely. Mr. T. S. Ware was first for twenty-four trusses of hardy herbaceous flowers. Messrs. Paul and Son, The Old Nurseries, Cheshunt, second. Mr. A. Gibson occupied the first place in the class for twenty-four stove and greenhouse flowers; Mr. W. Bates, gardener to Mrs. Meek, Poulett Lodge, Twickenham, second; *Anthurium Dechardi* was noteworthy in the collection of the last-mentioned, both the spathe and spadix being pure white and well developed. An interesting feature was the class for wild flowers; Mr. M. K. Dixon, gardener to Sir T. M. Wilson, Uckfield, being first. Mr. D. Phillips came first for twenty trusses of show *Pelargoniums*, and in the corresponding class for show varieties Mr. C. Turner was to the front.

NEPENTHES AND SARRACENIAS were of average merit. The former were placed on small stands, so as to show off their pitchers; this is far better than placing them on the ground, as we occasionally see them. Mr. H. James was first in the class for twelve *Nepenthes*, the specimens well grown; and the same exhibitor secured the premier prize for *Sarracenias*.

FERNS.—These call for no special mention. Mr. A. Offer was first in the class for six, closely followed by Mr. H. Eason; the former had good specimens of *Cyathea dealbata* and *Adiantum farleyense*; the latter had capital plants of *Davallia Mooreana* and *Gymnogramma chrysophylla Lauchena*.

FINE-FOLLAGED PLANTS were contributed by Mr. J. Cypher and Mr. H. James, who were first and second respectively in the class for six; in the corresponding class for amateurs Mr. D. Donald was to the fore, followed by Mr. A. Offer. Mr. H. James was first for six variegated-leaved plants; *Phormium tenax variegatum* and *Alocasia macrorrhiza variegata* were good; Mr. R. Butler second with specimens neatly grown.

NINETENTH CENTURY PLANTS.—There were four classes for these, but there was little response. In the class for a collection of annuals and hardy herbaceous plants, Messrs. Paul and Son, Cheshunt, were the only competitors. The group was large, and comprised a fair selection of plants introduced during the present century, noteworthy being *Henierocallis Middendorffiana*, certificated at South Kensington last Tuesday, and the showy *Papaver umbrosum*.

Fruit.—This was neither plentiful nor, on the whole, satisfactory, and in most of the classes there was little competition. Mr. R. Parker, gardener to Mr. J. Corbett, was first for a collection—the Black Hamburg and Foster's Seedling Grapes were fine; Mr. T. Hare a close second. Grapes were of average merit. For three bunches of Muscat of Alexandria, Mr. P. Feist, gardener to Mr. R. J. Ashton, first, the

berries large and well coloured. In the other class for white Grapes, Mr. W. H. Ward came to the front; his bunches of Buckland Sweetwater showing careful cultivation. The Black Hamburgs shown by Mr. J. Hollingworth were models of good culture, the bunches well shaped and the berries finely coloured; Mr. T. Osman, who was second, had bunches wanting finish. Mr. W. H. Ward was first in the class for three bunches of black Grapes, Black Hamburgs excepted. Fairly good bunches of Black Prince were staged, a Grape that is now seldom grown. In the class for a basket of white Grapes, Mr. P. Feist occupied first place; and in the corresponding class for black, Mr. J. Hollingworth was the most successful exhibitor. There were also classes for Melons, Nectarines, Peaches, Strawberries, and Pines, Messrs. H. Ward, W. F. Smith, R. Parker, W. H. Diver, J. Worthing, and J. Harris sharing the principal awards.

MISCELLANEOUS COLLECTIONS were numerous and full of interest. Messrs. F. Rivers and Son, Sawbridgeworth, received a small silver medal for a large group of fruit trees in pots, comprising Pears, Apples, Nectarines, Peaches, Cherries, and Plums, all bearing freely, and in the best of health. A small silver medal was also given for an extensive display of Gloxinias from Mr. A. Luff, Hethersett, Streatham; the plants were well grown and arranged, but being placed in a glass corridor in the full sun, the flowers were spoiled by the strong light. Mr. T. S. Ware, Tottenham, had an effective group of hardy perennials and Peonies. Large bronze medal was awarded. Messrs. Barr and Son, Covent Garden, received a like reward for their fine bank of Irises, Ixias, Pyrethrums, and other seasonable subjects. A bronze medal was awarded to Messrs. Hooper and Co., Covent Garden, for a collection of Irises, &c. The same firm were also granted a large silver medal for a tastefully arranged group. Messrs. Collins Brothers and Gabriel showed a small group of Pyrethrums, Lilies, and Ixias; and Messrs. W. Bulchin and Sons exhibited a basket of the brilliant blue *Leschenaultia biloba* major. Messrs. Paul and Son, Chesham, sent *Rhododendron Fortunei* Mrs. Charles Butler, described in our report of the Royal Horticultural Society's meeting. The same firm had several boxes of Pyrethrums. Messrs. Kelway and Sons, Langport, Somerset, exhibited a fine display of double and single Pyrethrums, several of them new varieties. Pansies displaying a striking variety of colours came from Mr. John Forbes, Hawick, N.B. A bronze medal was awarded the *Comte de Paris* Shreen House, Richmond, for hardy Orchids grown in the open air at the Chateau d'Eu, France.

Messrs. J. Laing and Co., Forest Hill, had an effective arrangement in the principal tent, consisting of Begonias, Orchids, and Ferns admirably intermixed, the whole backed with foliage plants. A large silver medal was awarded. Mr. G. Elliott, gardener to Mr. W. F. Parnell, Devonshire House, Stamford Hill, was awarded a silver medal for an interesting group of Orchids, including several fine varieties. Mr. W. May, gardener to Mr. F. C. Jacob, Stamford Hill, was also awarded a small silver medal for an interesting group of Orchids; *Thunia Marshalli* and *Anguloa Ruckeri* were noticeable. A small silver medal was awarded to Mr. H. B. May, Dyson's Lane Nursery, Edmonton, for a collection of Ferns—*Pteris cretica* Mayi, *Pteris cristata* compacta, and *Adiantum Paucoti* being noteworthy. We must not omit to mention the *Calceolarias* from Mr. D. White, gardener to Mrs. Watson, Redlees, Isleworth, which represent a dwarf, compact strain; the flowers are large, and exhibit a great diversity of bright colours. Mr. J. Douglas showed *Primula imperialis*, found near Choombie, Himalayas, at an elevation of 11,000 feet, and growing on the banks of streams.

Mr. Gordon, nurseryman, Twickenham, staged a very interesting group of Japanese Acers and Moutan Peonies, the latter being apparently a distinct race from the Chinese; the flowers were for the most part single or semi-double, and the colours novel. A few of the most notable were Princess Louise, bright carmine; Prince Albert, clear scarlet; Rifleman, deep maroon-purple; Princess Beatrice, large, white flushed with pink; Princess Alexandra, large flower, white, blotched at the base of each

petal with rosy purple; Lady Cordelia, semi-double, creamy white, flushed with flesh colour in the centre.

NEW PLANTS were numerous. Floricultural certificates were awarded as follows: To Messrs. J. Laing and Co. for Begonias Duke of Edinburgh, single, flowers of immense size, crimson; Duchess of Edinburgh, single, orange-scarlet; Princess Louise, white, single; Scarlet Perfection, scarlet, double; Terra Cotta, rosy scarlet, double; Marginata, very double, salmon-pink and white; Alba magna, double, pure white; Mrs. Aphorpe, double, rich pink; and Princess Royal, yellowish tint, double. To Mr. C. Turner for Pelargonium Iona, a beautiful fancy variety, upper petals rosy red, lower suffused with a lighter shade; and P. Ambassadors, a bright rose and white fancy. To Mr. E. B. Foster, Clewer Manor, Windsor, for Pelargonium Duke of Clarence, certificated by the Royal Horticultural Society, and P. Marion, a well-finished show flower, upper petals velvety purple, lower rosy pink. To Messrs. Kelway and Son, Langport, for Pyrethrums Florentine, Magician, Aphrodite, and Figaro, all described in our report of the Royal Horticultural Society, and Meny Hampton, a rich crimson single variety.

Botanical certificates were awarded to Messrs. J. Veitch and Son, Chelsea, for *Rhododendron luteo-roseum*, large trusses of rosy pink flowers; *Adiantum Capillus-veneris* var. *Mairisi*, free grower, fronds elegant, pinnales large; *Diplazium bians*, a graceful Fern, bold, arching fronds; *Abies canadensis argentea*, young growth light green, pleasing; *Juniperus canadensis aurea*, dense habit, yellowish green leaves; *Abies excelsa mutabilis*, a distinct Spruce, light green young growth; *Thuja gigantea aurea*, neat growing, foliage tipped yellow; *Ilex Aquifolium insigne*, leaves long, narrow, distinct; *Sequoia sempervirens alba spica*, young growth almost white, effective, and *Viburnum plicatum*, well known. To Mr. Blair, Treutham, for *Odontoglossum crispum*, Blair's variety, described in our report of the Royal Horticultural Society; to Mr. R. B. White, Gardloch Head, N.B., for *Dendrobium polyplebium*, small rose-coloured flowers; to Messrs. Sander and Co., St. Albans, for *Masdevallia grandis*, a rich crimson variety of Harryana; and *Odontoglossum crispum albanense*, flowers blotched with light brown on yellowish ground; to Mr. Bethell, gardener to the Duke of Marlborough, for *Cattleya Mendeli limbata*, sepals and petals rose colour, lip crimson-purple; to Mr. W. Chitty, Stamford Hill, for *Coleus Jubilee*, leaves large, dark chocolate-brown, midrib and nerves rosy crimson; to Mr. G. Elliott, gardener to Mr. W. Darnell, Devonshire House, Stamford Hill, for *Cattleya Mossiae*, Darnell's variety, sepals and petals pale pink, lip purple.

A prize list will be found in our advertising columns.

We understand that there will be an exhibition of Roses and Carnations at Troyes, France, on July 2 and 3. English horticulturalists are invited to exhibit.

Rating of nurseries.—I find that the Royal Horticultural Society has called a meeting for the 28th inst. at three o'clock. With the view of consulting the convenience of nurserymen and others who are desirous of attending the meeting called by my association, I have arranged to postpone the hour of meeting from four to six o'clock.—F. C. GOODCHILD, Secretary.

The Oxford Carnation and Picotee Union.—The third annual exhibition of Carnations and Picotees held by this flourishing union is announced to take place on Tuesday, August 2, in Mr. E. S. Dodwell's garden in the Stanley Road, Oxford. Carnations and Picotees that are somewhat late are rapidly making up for lost time under the influence of the bright sunny weather we are now enjoying.

Marketing cut flowers.—Messrs. Draper send us an illustration of the ideas people have of marketing flowers—a little box of poor weak *Ranunculus*, not a handful, and of no value whatever. To see, someone thinks worth while to make a market transaction of! People who want to sell flowers should learn some of the simplest conditions of the market.

Destruction of crickets.—"H. G." in THE GARDEN June 4 (p. 521) asks for a means of exterminating crickets. My gardener has recently quite by accident discovered a capital trap. Let "H. G." take a biscuit tin and put some canary seed in it, and so place it that the top is level with the floor (mine is on a step which happens to be just the height of the tin). Into this the crickets throw themselves; their return up the slippery sides is impossible. This trap has been fatal to scores and many mice as well.—G. F.

Corrugated iron for staging.—I find that many market growers are using this material largely for stages. It doubtless possesses many advantages over any other material that is generally used for that purpose. It is, of course, imperishable, and is very easily fixed, requiring merely to be laid on supports, lapping one piece over the other. Slate is too costly where profit is the object, and wooden stages do not in a general way find favour with market growers, both on account of their tendency to decay and the difficulty there is in maintaining moisture round the roots of the plants placed on them. The advantages to be derived from a cool, moist bottom for the pots to stand upon are so great, that many of the best London growers have long adopted the primitive form of standing the plants on the bare earth. Not long since I visited a market garden where enormous quantities of pot plants were in the rudest possible health, and out of about forty houses there were not more than four fitted up with staging. In some instances the stage was formed by digging out the path, but in the greater portion of the houses a brick wall was run down on each side of the path, the beds thus formed being filled up within a few inches of the top with soil, and finished off with ashes. When corrugated iron is used it can be covered with shingle, Cocoa-fibre, or anything that the grower may think will answer the purpose.—J. C. B.

Death of Mr. F. R. Kinghorn.—We regret to announce the death of Mr. F. R. Kinghorn, aged 75, at the Sheen Nurseries, Richmond, of which he had been proprietor since 1855. He was born at Lemoxlove, N.B., in February, 1813, and commenced his gardening career at the nurseries of Messrs. Ballantyne & Son, of Dalkeith, and after filling situations in private gardens, at the age of 21 he came south to Twickenham, as head gardener to Mr. A. Murray, at Orleans House, which was subsequently sold to the Earl of Kilmorey. Mr. Kinghorn retaining his post of gardener. It was while here that he zealously devoted himself to the improvement of some popular flowers, and especially was he successful in obtaining variegated forms of the zonal Pelargonium. One of his earliest seedlings was Countess of Warwick, followed by Flower of the Day, which retained its popularity for many years. The old pink Pelargonium Christine, as also several tricolour varieties, likewise a few *Azaleas* and *Epacris* were raised by Mr. Kinghorn. The *Calceolaria* was greatly improved by him, and he also raised some charming varieties of herbaceous *Lobelias*. In 1855 he established himself in business as a nurseryman at Sheen, and carried it on until failing health necessitated lessened exertion some four years ago. Mr. Kinghorn is succeeded by his only son, Mr. John Kinghorn.

Death of Mr. A. McIntyre.—We also have to announce the death of Mr. McIntyre, in his 59th year. Mr. McIntyre was until lately superintendent of the Victoria and Greenwich Parks—a post he held for about thirteen years, and from which through failing health he was obliged to retire. Mr. McIntyre's work while in this last position was eminently successful.

From a notice received we learn that the Royal Gardens, Kew, will be opened on Jubilee day, June 21, at 10 o'clock.

We understand that the coloured plates issued in "Familiar Wild Flowers," "Familiar Garden Flowers," and "Familiar Trees," are about to be used at the museums at Kew Gardens.

Flowers from Ireland.—We have received a gathering of flowers, consisting of *Veronica Hulkenana*, *Rosa rugosa*, *Malva* sp., &c., from Ireland. They had all been grown in the open air. The spike of *Veronica Hulkenana* was very fine.

Rose Canterbury Bells.—Mr. Christian, Hornwood, Chislehurst, sends flowers of delicate rose-coloured Canterbury Bells, all very nice in colour, and deserving attention from our flower gardeners.

Ornamental fish pond.—I have made an ornamental fish pond 50 feet by 24 feet; average depth 3 feet, well puddled with clay. What are the best means of preventing the water becoming foul from stagnation? Are there any aquatic plants which would tend to keep the water wholesome for fish?—CROYDON.

Names of plants.—J. Kennard.—Cannot name Strawberries from leaves and flowers.—L. K. L.—*Isolobos tataricum*.—J. C. Wheeler.—Specimens too much shrivelled for identification.—R. C.—*Epinidium pinnatum*.—G. Baber.—*Polonium Richardsoni*.—C. L. Hayward.—All varieties of *Scilla nutans*.

WOODS & FORESTS.

"YORKSHIREMAN."

THE AUSTRIAN PINE.

(PINUS AUSTRIACA.)

LIKE the Corsican Pine (*P. Laricio*), this tree has of late years attracted a considerable amount of attention, not only from its perfect hardihood, even when planted under what might be considered unfavourable circumstances, but from its ornamental appearance, and the great amount of shelter it affords to other less hardy kinds. Here it has been planted by the thousand at all altitudes, from a few feet above sea-level up to about 1000 feet, and in all these situations it has done well—in fact, proved itself to be one of the most valuable Pines yet introduced to this country. For planting by the sea it is an invaluable tree, flourishing well down even to high water mark, and that even in situations where, from the violence of the winds, few other trees could succeed; and as it is by no means partial to a rich soil, this gives it a great advantage over many of its fellows for planting in the poverty-stricken districts, such as occur around our coast lines generally. Then for high-lying, wind-swept districts it is very suitable, its strong, hardy nature and stiff-set foliage rendering it peculiarly well adapted for withstanding the climatic influences at such elevations. We have used it largely in the formation of a plantation at 700 feet altitude, principally on the south-western side, from which quarter our worst winds blow, and with perfect success. It acts as a stout wind-barrier and useful protector of other excellent timber trees that would not, without the aid of the Austrians, have attained to anything like their present dimensions at so high and exposed an altitude. For bog-planting, the Austrian Pine is one of the best trees I know of, growing far more freely than others planted on even the best quality of loam. How its timber produced on bog may turn out I know not, but in judging from specimens of hardly a quarter of a century's growth as compared with those grown on loam, the difference was imperceptible.

Limestone districts, in judging from its native Austrian hills, would, no doubt, suit the requirements of this Pine admirably, but I have no statistics of its growth in such soils. As an ornamental tree the Austrian Pine is certainly not behind many of its neighbours, its wealth of dark, glossy, and shaggy foliage, and pleasing contour generally being admired by all. For planting in clumps or masses it is particularly well suited; indeed few of the Pines form a more striking feature of the landscape than does this tree when suitably arranged in irregular clumps. Single specimens when allowed plenty of room on the greensward are highly attractive, and produce in an incredibly short space of time globose masses of the richest green foliage, and which contrast strangely with other Conifers of a light or silvery appearance. The Austrian has, however, one fault, and a bad one, too—it is very apt to get top-heavy, and as its roots spread horizontally, not unlike those of the common Spruce, it soon becomes a victim to the first severe storm. Single trees are most apt, I have noticed, to get overturned, and the evil rarely occurs where this Pine is planted in quantity, and at no great distance apart.

From its close habit of growth this tree makes an excellent screen fence, but to form such in a really satisfactory manner it must be allowed plenty of room, so that the lower branches become perfectly developed, and a marked peculiarity of this Pine is that the lower branches do not, as in many species, die away as the tree advances in age, but remain fresh and green if allowed a free circulation of air. For obstructing the view of any unsightly objects, such as a quarry, old buildings, or objectionable dwelling-houses, this tree may be used with freedom, for few others could serve the purpose so well.

As a timber-producer the Austrian Pine is not without value, and several experiments made with the wood prove that it is very durable, and one of the

few that may be used satisfactorily where it is subject to being wet and dry alternately. Some years ago we cut up two large trees of the Austrian Pine for this purpose, and placed the planks side by side with those of the Scotch and Spruce Firs to hold up the ever-sliding banks of a river, each being marked and noted down for future observations, and on examining these a few days ago the Austrian timber seemed quite sound, but of lighter colour than when placed in position. Sufficient time has, however, not yet elapsed for us to speak with any amount of assurance as to the superiority of the wood of this tree over that of either the Scotch or Spruce Firs, but from the present appearance of gates, stiles, &c., manufactured from the timber some years ago there can be little doubt but that it will, so far as lasting qualities are concerned, be quite equal to either of the other two. The timber of the Austrian Fir grown on this estate is far more resinous than any other British wood that I have seen cut up; it is likewise remarkably strong and tough, although coarse in the grain.

It works well under the tools of the carpenter and takes a nice polish. To produce good and clean timber the Austrian, like all other members of the Pine family, must be grown thick—so thickly together that the lower branches will be killed by Nature's system of pruning. I have had large Austrian Pine trees grown along the outskirts of a wood, where their lower branches were, from having plenty of light and air, allowed to remain in a healthy growing condition, cut up for boarding, but the difference between these and such as were cut from trees grown closely together in a wood would hardly be credited. This has proved—to me at least—that to produce nice, handsome clean specimens feathered to the ground, the Austrian Pine requires plenty of room to extend its strong rambling branches; but where the production of good, saleable timber is the end in view, then grow the Austrian Pine close—so close that the lower branches will be killed outright, and for fully half the length of the main stem.

Judging from the size of many of these Pines in the park here, I should say that they must have been planted shortly after the introduction of the tree in 1835. Several of these have a girth at a yard up of fully 7 feet, and long, clean stems containing a considerable quantity of clean, well-grown timber. The branches are usually long in proportion to the tree's height, stout, and well furnished with dark green, tufted foliage. Two leaves are in each sheath, and usually 5 inches long, while the cones are 1 inch long in the majority of specimens. That this tree is not specifically distinct from *Pinus Laricio* I have been long ago convinced, although the typical *Laricio* differs in many well marked technicalities from the commonly cultivated Austrian Pine. For all this, I can show to any person who may be interested in the matter all gradations in foliage and appearance between the typical *P. austriaca* and *P. Laricio*, and point out specimens whose nomenclature will puzzle even the most learned in these matters. The twist at the base of the leaves of *P. Laricio* goes for nothing, neither do shape of cone nor peculiarity of bud structure, as all these I have carefully studied in connection with the trees. It is, perhaps, enough for the tree-lover to know that, whether for ornament or use, the representatives usually seen of each so-called species are distinct, and sufficiently so for certain ends, so here I will let the matter rest.

As to the nursery management of *Pinus austriaca*, that is simple enough, for by sowing the seeds in a well prepared bed out of doors they germinate quite readily, and the young seedlings are at the age of two years fit to be lined out in the nursery border. Frequent transplanting induces the formation of good roots, and plenty of them, so by all means attend to this point, and the final transplanting will be attended with good results. This, indeed, transplants better than the majority of Pines when of large size, say up to about 6 feet in height, and for this reason it is usually kept as a stock plant in the nursery for filling up gaps in the woodland caused by blown-over trees. Such plants must, however, be well

attended to in the way of frequent transplanting, for if this is neglected the rootlets are few, and consequently the final moving is attended with risk. Here, unfortunately, are rather fond of the Austrian Pine, and we have frequently felt grieved to see plants nibbled, and, in some instances, quite destroyed by their depredations. Davidson's compost or coal tar we have found useful to a certain extent, but to be really efficacious either must be often applied.

A. D. WEBSTER.

SHALLOW V. DEEP PLANTING.

MORE failures occur, in my opinion, through deep planting than from any other cause, and yet it is far wiser to err on the right side and plant too shallow than too deep, for in the former case the plant can assist itself; in the latter it is helpless. The roots of plants, as well as the parts above ground, want air and warmth, and if properly accommodated, will soon adapt themselves to the place in which they are to grow. If the surface soil is naturally dry, the roots will run down after moisture, and if it is wet, they will spread near the top, but in no case can a tree or plant, except such as strike root at every joint, flourish if the collar is much below the surface. In planting small trees or shrubs, over which the wind has no power, there is no excuse for deep planting, not even the plea of saving trouble, yet we often meet with even small shrubs planted far too deep.

Many practise deep planting because they imagine it saves trouble and time in staking the trees, to secure them from the effects of high winds. To remedy this, they plant them down low enough to tread them firm, and while they thus save the trouble of supports, incur risk of failure and the certainty of damage, for when a plant or a tree is not of a nature to strike out roots at a proper distance from the surface, it cannot flourish; it may exist for a time, but will eventually die. On the other hand, if a plant is merely held upright on the surface, and its roots spread round it, and a few inches of soil put over them, they have power to strike down, and this they will do to the necessary distance to afford support.

Of course, all trees over a certain height require to be made firm by staking, or some other method, to secure them from the effects of high winds; otherwise much injury frequently occurs. Hundreds of persons have to complain of the effects of deep planting in the frequent failure of their trees and shrubs. Everything seems to go wrong with them; whilst they remain in ignorance of the real cause, which, in many cases, is deep planting. Now, although we may fearlessly assert that thousands of trees and shrubs are annually sacrificed from this cause, more especially where planting is carried on by large contracts, there are many losses occasioned by gross carelessness of another kind, as, for example, taking up the plants badly, chopping off the extremities of the roots, allowing them to dry after they are taken up and before re-planting, neglecting to tread the earth firm and pressing it in between all the roots, or allowing the wind to move them backwards and forwards till every fibre is disturbed.

Deep planting, however, is the most prolific source of damage; and this is to be seen most conspicuously in fruit trees. In planting I would direct attention to the following: On no account plant anything deeper in the earth than it has been before; let the collar of the root be level with the surface of the ground, or, if in wet situations, above it. If the roots are spreading, loosen the earth, spread the roots round the stem, throw from round the spot enough of the best soil to sustain them, and heap it up round the stem so as to be just even with the collar, which is, in all well-grown nursery plants, the mark which shows the depth at which the tree stood before. Staking, in the case of tall trees and plants, I have referred to above. Be just as particular with small plants, which, if planted at a right depth, instead of having to struggle against disadvantages until the roots accommodate themselves to the ground, will at once start into healthy growth.

E. B.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakspeare.*

ROSE GARDEN.

T. W. GIRDLESTONE.

ROSES IN PARIS AND LONDON.

ONE must hardly go to Paris to see Roses. I tried hard to see some of the best near Paris, but the season there as well as here is three weeks or more later, and so there were no Roses in flower in the open in the early part of June. The Roses at the exhibition in the Champs Elysée were not of much note, though forming very effective masses or fringes to other plants. I also missed seeing some of the more choice collections of Roses near Paris through losing my way to Bourg-la-Reine, and there seems a regular scarcity, almost an absence, of Roses in the public parks and boulevards of Paris. This is the more to be wondered at, as there are some capital Roses in the Jardin des Plantes, which is surrounded by streets and houses. The plants were strong and vigorous, and promised a fine flower, neither were aphides, grubs, mildew, nor rust visible. There is an abundant promise of coming beauty, but looking down on these fine Rose borders in the first week of June it seems doubtful if much of this beauty will be revealed till very late in the month. The most popular Roses in France, judging by the markets, are the *Maréchal Niel* and several varieties of the dwarf miniature Provence, probably *Dr. Meaux*, and the dwarf Burgundy. It seems singular, considering how useful white is for contrast, that I did not see a single bunch of the White Burgundy. But these tiny Roses are a puzzle to the Britishers altogether, and it is a mystery to us how a nation can go on growing acres on acres of those tiny Roses when they might grow, say, *Gloire de Dijon* with equal ease and success. These small Roses seem rather earlier on the whole, but then the *Gloire de Dijon* is a long way ahead in size and colour and even fragrance, though the dwarf tiny Roses are pretty for a change, their very smallness commanding a certain amount of admiration. But the growers mostly hasten to destroy their merits on this head as far as they can by bunching the Lilliputian Roses up into huge bouquets from half a foot to a yard in diameter, as if supremely anxious to develop at once their taste and power in forming masses out of small material.

A few Niphetos and other light-coloured Teas were visible in the markets and shops, and a profusion of Cabbage and other Roses, mostly in embryo buds, appeared in the battle of flowers indulged in at the *fête* of flowers held in the Bois du Boulogne on behalf of the victims and sufferers from the Opera Comique. The fully opened Roses used in this battle were, however, grown under glass or brought from the southern parts of France or Italy, as the Roses around Paris were, as already described, in a similar flowerless condition to those in England. Such being the case, and not being able to see the Roses at Manchester or other early English exhibitions this season, it so happened that my first introduction to good Roses this season was at Buffalo Bill's Wild West Show at West Kensington. Amid the almost bewildering variety of exhibits that found a place in this most interesting exhibition, it was quite refreshing to find a tent well furnished with Roses in pots by Mr. W. Paul, of the Waltham Cross Nurseries.

I made a hungry rush for Her Majesty, but she was not in flower, and seemed all unconscious of the beauty and fragrance that was expected of her this year of jubilee. The Bride had been in bloom; The Puritan's time of demonstration and ovation was not yet. However, if The Puritan is in very deed the direct lineal descendant of *Devoniensis* and

Mabel Morrison, with the former preponderating, as the wood seems to indicate; and if, moreover, its flowers are cushioned in leaves, as its habit renders possible, and its perfume is distinct and delicious, more like a Magnolia than a Rose, and it gets rid of all its yellow in the opening, and is as white as snow when fully expanded, then must Niphetos and such popular and now white Roses as *Madame de Watteville* look to their laurels if they are to hold their own before such strong competitors as *The Puritan* and *The Bride*. Experience sustains the character of *The Bride* as neither more nor less than a white sport of *Catherine Mermet*, with all the good qualities of the latter; and more need hardly be said in its praise. *The Meteor* is a Hybrid Tea Rose strongly recommended by this firm as possessing the positive merit of being red without dash or mark of purple, which injures so many of this class or section of Roses. *W. F. Bennett* is another red or crimson Hybrid Tea beautiful and brilliant in bud, and likely to become popular for forcing and marketing. It seems, however, somewhat tender in the open air, as most of our dormant buds were killed this winter, though protected, as other Teas, with *Bracken*. As a satiny rose-coloured Rose with a brighter centre, *Clara Cochet* is a vigorous growing Hybrid Perpetual likely to have a useful future for pot and open-air culture.

The following, among others, were shown by Mr. Wm. Paul at West Brompton: *Alphonse Souper* (H. P.), similar in form to the old and useful *La Reine*, bright rose; *Captain Christy* (H. P.); *Comtesse de Castoja*, said to be a seedling from *Alfred Colomb*, showing most of the good qualities of the latter; deep scarlet, full and imbricated. *Countess of Rosebery* and *Duchess of Bedford*.—These excellent Roses are too well known to need description. *Crown Prince*.—This is a most showy Rose for pots, garden culture, or forcing, though not full enough for showing; large double; colour, a brilliant mixture of purple and crimson. *Eclair*, a bright red Rose in the way of *Charles Lefebvre*. *Emperor*, very dark, small; excellent for button-holes. *Francisque Rive*.—This is specially fragrant, large, bright cerise-rose, shaded with carmine. *Gloire Lyonnaise*.—This fine-formed, fragrant, Tea-looking Hybrid Perpetual must by no means be confounded with the canary-yellow Tea Rose *Belle Lyonnaise*, this being a large, full, almost pure white Perpetual, slightly tinted with yellow. *Lady Sheffield*.—This fine exhibition Rose is also one of the best for pot culture; form of flower almost perfect; large, full, and of great substance, and of a brilliant cerise colour. *La France*, *Lord Macaulay*, *Madame la Baron de Rothschild* (otherwise *Baroness Rothschild*) and *Madame Gabriel Luizet* need no description or commendation, only that the latter is one of the sweetest Roses in existence, and admirably adapted for pot culture on that account, as well as for its perfect cupped form and extremely soft and delicate pink colour. *Magna Charta*, *Marie Baumann*, *Marquise de Castellane*, and *Merveille de Lyon* have only to be named to be appreciated. *Masterpiece* is one of Messrs. William Paul and Son's seedlings from *Beauty of Waltham* of a few years back, and is a brilliant pot Rose, with large flowers of a good shape and a rich rosy crimson colour. *Pride of Waltham*, *Prosper Laugier*, and even *Queen of Queens*, another fine Rose raised by this firm, are too well known to need description, however brief. The latter is said to be almost a new departure, a cross between a Hybrid Perpetual and the old *Maiden's Blush*, retaining much of the soft colouring of the latter in its soft pink edged with blush, and the best qualities of the former in its exceptional floriferousness, every shoot being crowded with flower-buds. *Souvenir de Madame Robert*, a delicate salmon-rose, with a bright centre, is less grown than it deserves; and *Star of Waltham*, *Ulrich Brunner*, *Violette Bouyer*, *William Warden*, &c., added to the beauty and variety of this interesting display of Roses. Among Teas the following were the most conspicuous: *Catherine Mermet*, *Etendard de Jeanne d'Arc* (a creamy white seedling of *Gloire de Dijon*), *Hon. Edith Gifford*, *Lady Mary Fitzwilliam*, *Madame Chedane Guinoisseau* (a pretty canary Rose with a

tremendous tinge), *Madame Lambert*, *Souvenir d'Elise Vardon*, *Sunset* (a deep apricot-coloured sport from *Perle des Jardins*), &c. A few choice *Rhododendrons* and variegated trees and shrubs mixed with the Roses added to the general effect, and altogether the well-furnished tent proved a welcome and refreshing addition to this great exhibition of American life and products.

D. T. F.

AMONGST THE ROSES.

WE gathered the first bunch of Roses from open walls on May 27, which is rather later than usual for this part of the west of England. The choicest flowers were the Tea-scented varieties from a low wall facing south; the sorts were *Marie Van Houtte*, *Shirley Hibberd*, *Madame Willermoz*, and *Madame Lambert*. From *Fortune's Yellow* I picked a nice flower. *Yellow Banksian* and *Gloire de Dijon* were from a wall with an east aspect. In every case the flowers were perfect and the plants in the most promising condition. The following Teas have stood the winter well: *Etoile de Lyon*, *Belle Lyonnaise*, *David Pradel*, and *Catherine Mermet*. While on the subject of Tea Roses I may refer to the pruning of this section, because there is a great difference of opinion on this subject. Some cultivators maintain that they should have but little pruning, while others recommend the growth being cut hard back. My own opinion is that Tea Roses will submit to hard pruning and in time flower freely, but if early flowers are wanted the less pruning the plants have the better. All the cutting back my plants had was just the dead tips of the shoots taken off in the spring. To set them right for the winter, I went over them late in the autumn and cut away here and there a shoot, otherwise they were left almost alone. The flowers I cut on the above date were on the short spray growth, which was left unpruned, while none of the branches which had been shortened back were showing a flower-bud, because they have not had time to make sufficient growth. To give another instance in favour of moderate pruning, I may point to *Gloire de Dijon*. The earliest flowers came from the shoots which were laid in nearly or all their length. On the same principle, I hold that other Tea Roses should be pruned if early flowers are wanted, but where the time of flowering is of no consequence, large plants of this section may be cut back as severely as the Hybrid Perpetuals. To keep the plants from becoming too large, prune them as soon as the first flowers are over. They will then have ample time to become well furnished with wood that will bear flowers early the following year. It will do the plants no harm to shorten back the branches at midsummer.

The condition of Roses in beds and borders at the present time is very satisfactory. There is no mildew and but very few Rose maggots. The foliage is, therefore, clean and bright. Speaking of the foliage of Roses, I have been struck with the remarkably handsome leaves on *Rosa rugosa*. They are of a pleasing green colour, and the plant would be worth growing merely for its leafage. All the varieties are alike in this respect, and large bushes have quite an imposing effect. In the autumn the leaves change to deep yellow and rosy crimson, which, with their dark red berries, give them a very attractive appearance. Another valuable feature in these Japan Roses is that they will thrive where the Hybrid Perpetuals refuse to grow. There is also a great difference in the colour of the leaves of some of the Tea Roses, when they are grown out of doors, as compared to those under glass. The young growth on such varieties as *Etoile de Lyon*, *Shirley Hibberd*, and *Safrano* is very much darker, being of a deep bronzy red.

J. C. C.

Maréchal Niel Rose.—When on warm walls with a southern aspect, this Rose breaks into growth so early that it is often cut back by late frosts. I had an instance of this in the spring. There was a show of fine buds, but the frost killed every one; the plant itself has suffered no material harm. A plant in another situation which did not

commence to grow so early by a month, has several buds at the present time. We used to have a plant on a wall facing east, which made splendid growth and covered a large space. We tried several methods to secure a plentiful display of flowers to stand, but never could. One season we covered the plant until the flowers were a good size; then we had a spell of cold weather, the wind being in the east, and, owing to the exposed situation of the Rose, every bud was killed, although there were upwards of 200. Last season, after trying seven years, we decided to replace it with Gloire de Dijon. When living at Ashton Court upwards of twenty years ago a high north wall, sheltered by shrubs and trees, was covered with this Rose. In the spring the plants were a mass of bloom, the flowers large in size, and of good colour. I remember cutting many basketfuls to take to the house for decoration. Several other Tea Roses have succeeded quite as well. I do not remember if they were protected in winter or not. The plants when dormant do not, in my own case, suffer so much from cold as when growth is commencing; in fact, this applies to many things that are very beautiful, but difficult to manage. No doubt the Maréchal Niel Rose requires shelter, although I am not sure that a south aspect is best for it. I had a plant in this position that did well for several years as regards growth, but in early spring the blooms were all cut off, except where we trained the plants over the end of a vinery at work. These produced grand flowers.—JOHN CROOK, *Hants*.

Maréchal Niel in the open air.—I note at p. 512 that Mr. J. Muir gives a poor estimate of this fine Rose in the open, and one that I can by no means endorse from experience. Of course, a good deal depends on soil and site, and perhaps more on locality as distinct from both. But all three must surely be unfortunate where it can be said of the Maréchal "that the growths fail to develop freely, that the blooms rarely appear in any quantity, and that a good specimen of the Maréchal is seldom seen in the open air." Possibly some of these phrases are used in a special sense, and in contrast with enormous specimens under glass. I would venture to say of the Maréchal that throughout the greater portion of East Anglia and many other districts it grows freely and blossoms most profusely in the open air; hence, instead of its open-air culture ending in disappointment, some of the grandest flowers and most magnificent results have been obtained from Maréchal Niel in the open air. In the matter of colour, for example, the open-air blooms won by many points in a canter. The same may almost be said of substance. Out-of-door blooms have a solidity of substance and a thickness of texture that are seldom equalled under glass. Of course, out of doors as well as in, for that matter, the tenure of life in individual plants is capricious as well as precarious. But as I have had standards on the Brier a dozen years old, and dwarfs on their own roots and otherwise as old or even older, it must be admitted that the Maréchal is at times as long lived in the open as under glass. It is also, as a rule, a perpetual in the sense, at least, of flowering twice in the open air, while it only blooms once under glass, and those who will grow a dozen or a hundred Maréchal Niels in various aspects in the open air will seldom be without one or many blooms of this most magnificent of all golden Roses from May to November, while those who grow it under glass chiefly will concentrate their season of this finest of all golden Roses into the few months included between March and June.—D. T. F.

SHORT NOTES.—ROSES.

Rose The Pet.—An excellent little Rose, the flowers small, double, pure white, and freely produced. Plants in 5-inch pots have a pleasing appearance when in bloom, as the leafage is small and the growth neat. We saw it in fine condition at the Bush Hill Nurseries of Messrs. Low.—C.

Scotch Briars.—Beautiful both indoors and out; large bushes of the white and of its ancestor, the single Burnet Rose, are loaded with flowers. The many kinds—red, pink, and yellow—form a much variety, that it is worth making a little garden in some half-wild place or retired part of a garden for these alone. They have only one fault, namely,

that their blooming time is so short. They delight in poor, sandy soil, such as the Rose aristocracy disdains to grow in.—G. J.

NOTES ON ROSES.

NEW TEA ROSE LADY CASTLEREAGH.—We have received blooms of a beautiful Tea-scented Rose under the above name from the raisers, Messrs. Alexander Dickson, of Newtownards, Ireland. The variety is said to be the result of a cross between President and Marie Van Houtte, and appears to be a valuable acquisition, for the blooms sent are large, very evenly and regularly formed, and of great substance; the colour is a pleasing shade of soft rosy yellow, margined externally with more decided rose colour, and, judging from the magnificent foliage which accompanied the flowers, Lady Castlereagh must make an exceedingly handsome plant. The variety appears thoroughly distinct, and as the blooms sent were cut from a plant out of doors, there is every reason to believe that they are characteristic examples.

HER MAJESTY.—It is satisfactory after all the adverse criticisms from America and elsewhere of the flowering capabilities of this grand Rose to find both maiden and cut-back plants generally throwing strong bloom. Of a good many dozen maidens, both on Manetti and Brier cutting stocks, there is not a shoot which does not carry one or more flower-buds, and the same remark applies to the cutbacks. We expressed the opinion at the time that our American cousins' condemnation of Her Majesty should not be accepted without trial in this country, and we still confidently expect that their verdict will not be endorsed by English growers.

MAX SINGER (Lacharme).—This new cross between Rosa polyantha and General Jacqueminot seems likely to prove a valuable addition to the meagre list of red climbing Roses, for the flowers are larger and better formed than had been gathered from the first description, and instead of being, as there stated, borne singly, are always found in clusters of three or four. The flowers are above medium size, very full, and well formed, of a bright cherry-red colour, and very freely produced; the plant is of a vigorous climbing habit, with good foliage, and perfectly hardy, for several plants budded last June started and made shoots 2 feet or 3 feet long during the autumn, but were nevertheless uninjured by the severe winter, and are now flowering to the tips.

GRACE DARLING has again this year been the first to flower of what may be called the conventional type of Roses, and has been, and is, if possible, more bewitchingly beautiful than ever. Blooms upon plants in the open expanded even before the Teas on the south wall, and the exquisitely tender rose tint of the flowers, contrasted with their dark foliage and their brown-red stems, constitutes one of the most delightful Rose treats of the year.

THE AUSTRIAN BRIERS have been gorgeous during the last few days. The single yellow, and the copper as well as the semi-double Harrison's Yellow, have been literally masses of flowers, and are immensely popular for cutting. *Appropos* of the alleged fugitiveness in the cut state of these charming single Roses, a large dining-table was decked with them on Friday night; the decoration was used throughout the whole of Saturday, and was still bright and attractive at breakfast on Sunday morning. Not less than 150 blossoms were employed, which, thus, without any renewal, lasted upwards of forty hours—a period beyond which few Roses remain in a state of beauty during summer weather. The Scotch Roses are very gay, especially the yellow variety, and the blush Stanwell Perpetual, R. Woodsi, with its large trusses of single pink flowers, is very pretty; and so are the rugosa varieties, the variety called coruscans in particular, with its pale silky rose blossoms; while R. polyantha is solid with bloom.

Some good blooms of Tea-scented Roses are opening now in the sunniest situations, the best being Rubens, Niphotos, and Souvenir d'Elise Vardon; and the pretty hybrid Bourbon, Marie Paré, too seldom seen, is giving very good examples of its

pretty flesh-coloured and gracefully-formed flowers. This Rose is very well worth growing where a few early blooms are wanted out of doors, and it is admirably adapted for cutting. T. W. G.

Rose Lady Mary Fitzwilliam.—Being one of the earliest to endorse the high merits of this Rose, I was pleased to find "North Herts" eulogising its merits in THE GARDEN (p. 512). Our best flowers have been gathered from dwarfs on their own roots on walls, and very fine and chaste they have been. Our dormant buds on standard Briars were mostly killed by the frost, so we have not been able to write of their doings. This and some other circumstances strengthen my belief that this Rose will prove rather tender, but it will probably turn out to be one of the most valuable for forcing and general culture under glass.—HORTUS.

Rose The Bride.—I forward herewith a water-colour painting of the new Tea Rose The Bride, drawn from Nature by my daughter, Eva Beachey. The Bride is a sport from that well-known lovely Rose Catherine Mermet. It originated in America, and was sent out and described as a white Rose by the raiser. The blooms now figured are life size, and were grown on one of the original plants imported last summer. They arrived as very small-rooted cuttings, and though some failed to thrive well, others have prospered and made good plants. I find that cuttings of this Rose strike readily, and that it is as strong a grower as, and I fancy a freer bloomer than, its parent. It will be observed that it can hardly be called a white Rose, though to my mind the beautiful creamy tint towards the centre is no disadvantage, and one may say, without fear of contradiction, that it is "the lovelier daughter of a lovely mother," unsurpassed by any other Tea Rose for size, shape, and delicacy of tint. As a show Rose it is certain to take one of the highest places, owing to its staying powers, which are very great. Altogether, I think I may safely join in the choruses of those delighted rosarians who pronounce it to be "the Rose of the year."—R. W. BEACHEY.

THE DICTIONARY OF ENGLISH PLANT-NAMES.

TO THE EDITOR OF THE GARDEN.

SIR,—Mr. Jas. Britten's defence of his slander is not an honest or straightforward one. He says he never said the names were "inventions of mine," but in a "don't-nail-his-ear-to-the-pump" mode of delivery he simply said they were "inventions."

All plant-names are, of course, the inventions of some one or other. May I ask Mr. Britten what did he mean by asserting that "most of the names" in my "Dictionary of English Names of Plants" "are inventions" if he did not intend it to be distinctly understood that they were inventions *of mine* in order to discredit my book? This is the only idea that can possibly suggest itself to anyone who reads his words, and this assertion of his is, I repeat, "a downright and malignant falsehood." If Mr. Britten looks into Asa Gray's "Botany" or Sweet's "Hortus Britannicus," he will find dozens of such English names as "Michaux's White Alder," "Panicked White Alder," &c. What right has he to condemn my book for quoting such names from these and other standard works?

The local names of British plants which I have taken exclusively from Mr. Britten's book are very few in number, and occur chiefly in the earlier pages of my dictionary, the purpose of which was to bring within the compass of one volume English plant-names which were previously scattered through many books on gardening and botany, so as to form a perhaps useful book of reference for the uninformed public, who of late years have taken so largely to gardening. The "hole-and-corner" names of British wild plants, which are seldom or never heard outside their native parishes, and of which Mr. Britten's dictionary is almost entirely made up, are not very suitable for the object of my book, and it would be no loss to it if I expunged even the few that I have quoted.

I did not notice Mr. Britten's querulous complaint of "plagiarism" in the *Journal of Botany* (the copy of which, however, was not sent to me by him), as I was very busy at the time, and, besides, thought that the general acknowledgment (in my preface) of my obligation to "our standard botanical works," &c., was sufficient to any reasonable mind, the number of publications consulted by me being so great that I could not very well specially mention one to which I was only very slightly indebted.

W. MILLER.

MARKET SALES OF GLASSHOUSE PRODUCE.

THE growers of hothouse fruit will doubtless feel much satisfaction at the intention of Messrs. Draper to sell English-grown hothouse fruit by auction. It has long troubled those who send produce of this description to Covent Garden that they have no means of accurately ascertaining the exact market value of the same, when it is known that the retail price in the Central Avenue is just about double what is returned to the producer. I am not aware of any trade where the retail price is double of what is paid for the article in bulk, but I know that the price asked for many things in Covent Garden represents a profit of 100 per cent. I have seen Strawberries sold in the Centre Row at 20s. per pound, for which I received 10s. per pound. I have known Grapes to be sold at 10s. per pound, for which the grower did not get half that amount, and many similar instances have at various times come under my notice. If you complain, you are told that heavy losses are frequently experienced, that in a time of depression sales have to be forced at prices that do not admit of a margin of profit, and that the high prices asked now and then are simply used as a means of bringing things to a level.

At one time I grew Cyclamens for market rather largely. My plants were very good, and going into the market one morning I was told that they were fetching from 18s. to 30s. per dozen. When I settled up I was returned less than 1s. per plant all round. I found that others had been served just as badly. In very despair I gave up growing any quantity of pot plants for market, as I could not get a fair price, and did not care to go and sell myself.

When goods are sold by auction the grower knows what his stuff realises. If times are dull with correspondingly low prices, he has whatever comfort there may be in knowing that it is "neighbour's fare," and is not tormented by the thought that he may have fallen into bad hands. There is no doubt that in time the public sale of all kinds of market produce will become general. The dissatisfaction at the present state of affairs pervades all classes of market growers. I mentioned to a grower of outdoor stuff what was contemplated being done in the matter of glasshouse produce. "I wish," he said, "that someone would do the same with vegetables." The largest growers of vegetables and fruit in general sell their own stuff, or employ a man to do so. These men grow so much, that it pays them to attend to this matter personally. They, of course, are independent of the middlemen. They, too, form a connection, which, even in a public market like Covent Garden, has its value. The small grower does not enjoy these advantages. He has to depend entirely on others for getting rid of his produce. I observe in Messrs. Draper's instructions that Strawberries are to be packed in shallow boxes without punnets. I venture to assert that this plan will not find favour either with growers or with retailers. In the first place, the fruit never looks so well as when nicely put up in punnets, and the Strawberry is such a soft fruit, that there should be no handling of the berries from the time that they leave the grower until they come into the consumer's possession. I am certain that none of the London Strawberry growers will ever adopt this way of marketing their fruit. I should be very sorry to do so myself. There is also the retailer to be taken into consideration. Many greengrocers have to drive some miles to market; they have to get back and go their round early in the day. The time re-

quired to put up, say, 20 lbs. of Strawberries in half-pound baskets would be a serious item of labour. Some growers I know living in Jersey and Weymouth adopt the box system, but they would not unless compelled to do so. Messrs. Draper probably base their advice in this matter on their experience with the foreign produce, but this is, of course, an entirely different kind of fruit from the luscious handsome samples grown round London. The foreign Strawberries are only consumed by the poorer classes, or in the houses of the rich are used for the commonest purposes. The English-grown fruit has the place of honour, and must go into the consumer's hands without blemish. I cannot see that there is any need to depart from the time-honoured custom of "punning" the fruit. It only requires a little modification to render it suitable for public auction sale. The plan I should recommend is to use boxes which will just contain from four to twelve half-pound baskets. Let them be made so that there is just room to cover each basket with a whole Strawberry leaf or two. When the lid is put on, there will be just enough pressure to keep the fruit in place without in any way damaging it. With ordinary careful handling there can be no danger of the fruit getting injured. We pack our fruit in this way, about twelve pounds in a box, and never have a berry spoilt. There is one thing I should like to allude to, as I am sure that if this detail is not taken into consideration, the whole affair of selling glasshouse produce by public auction will collapse, and that is, there must be a guarantee from risk to goods in transit. No grower would send his produce to Covent Garden if he thinks that the packages are going to get the rough treatment that the foreign goods experience, both in coming to market and when they get there. English-grown hothouse fruit is too valuable for this. If the Messrs. Draper wish to encourage this form of sale they will have to do, as those who specially deal in home-grown glasshouse fruits do—they will have to arrange for meeting it at the railway terminus. I would not send a single parcel of fruit to any salesman if I knew that it was to be jolted over the London stones in a van. In the case of any large quantity it ought to be practicable to convey it without risk. Small lots can be carried in as is now done.

On the other hand, English growers will have to improve their way of marketing their fruit, taking a pattern in some respects from Continental growers. It is a prime consideration in auction sales that lots are to be made up to suit all kinds of buyers. The foreign fruits are generally sent with this object in view. Of soft fruits, such as Cherries, Strawberries, Peaches, Apricots, &c., the best samples at least are put up in packages of moderate size. This suits the purpose of those who only require small quantities. Another thing to bear in mind is honest packing. Continental growers make their samples uniform, so that in many instances purchasers here do not need to see before buying. A great deal might be done in this way with us. Most market growers are specialists, growing more or less large quantities of particular things. Taking Grapes, for instance, instead of putting some 8 lbs. or 12 lbs. in a box, if from 2 lbs. to 6 lbs. were put up, such quantities would be more likely to meet the needs of many greengrocers. To simplify matters, each box should have description and grower's name. Thus, "4 lbs. Alicante—Jones." This would serve as a brand, which in a short time would become known. In selling, it would only be necessary to open one box; the name in time would become a guarantee of quality. Some years ago I used to send Strawberries packed 10 lbs. in light crates. I sent a regular quantity through the busy season, and many of these crates were never opened in the market. The fruiterer knew by invoice the contents; the purchaser was assured of the quality of what he bought. The secret of the Continental grower's success is that he knows what will suit our market, and puts up his goods to suit buyers. He sends large quantities of uniform quality, and so obtains the confidence of the retailer.—J. C. B.

— As a consignor to the sales of Messrs. Draper, permit me to thank these gentlemen for their patience

and courtesy, as well as their well-meant efforts to assist private growers of little experience to realise the best prices for their goods. The private advice already tendered to some of us, which you have permitted them to make public (page 468) is likely to be of the greatest value. Package and packing cases are our greatest difficulties. With the latter uniform in size for the same class of goods, and the former more skilfully performed, matters will be in a fair way of being arranged to the satisfaction of all parties. The plan of selling the boxes with the goods is likely to settle the vexed question of packing boxes. Private growers have been in the habit of obtaining their supplies from the grocers' and confectioners' shops, and hence the diverse character of their packing boxes. As these are no longer returned, the supplies will soon be exhausted and the conveyers of flowers and choice fruit will perform be driven to the box manufacturers for cheap boxes of uniform size and quality for their different classes of goods. Manufacturers of these should advertise them of different sizes for different purposes at per dozen or per gross in your pages. Doubtless, were they to communicate with such experienced salesmen as the Messrs. Draper, these gentlemen could afford the makers valuable hints as to the most useful marketable sizes for Roses, Gardenias, Grapes, Peaches, Strawberries, Figs, &c. Certain it is that uniformity of size in the boxes is one of the greatest aids to perfect packing. Anyone packing fruit or flowers a few times in boxes of the same depth (this is the main point; the length and breadth would vary in proportion to the number of dozens to be sent) would specially learn how to pack perfectly, as each process would be but a repetition of the last. But with the boxes always varying in depth, the art of packing would take a long time to learn.

As unplanned boxes will answer well lined with wadding or paper, the timber merchants and proprietors of sawmills ought to be able to greatly undersell the grocers, who, since the demand for empties has become more urgent, charge 6d. a box for all sorts and conditions of the latter; some no doubt worth more and others little or nothing. They also vary so much in weight as to seriously affect and add to the charge for carriage. The timber merchants' boxes might be made equally strong, while probably weighing about half as much. As any reasonable number may be tied together, this adds considerably to the average strength of each box, though of course each box should be sufficiently strong to travel alone and protect the contents from injury. As to the latter, surely some pressure, official or otherwise, ought to be put on railway servants to induce them to take more care of such perishable goods. Should not the Messrs. Draper and other large salesmen make it a part of their business to sue the companies for damages when they found goods carefully packed seriously lowered in value through obviously reckless handling on the line? It has been my painful lot to stand on many platforms and note how packages of flowers and fruits have been pitched in and out of goods vans on to platforms and from thence into porters' barrows or delivery vans, and the marvel is that anything could pass through such an ordeal and yet be fit for sale, however carefully packed it might be. Were such reckless injuries charged for, as a matter of course, as regularly and constantly as well-packed pictures or glass broken or marred on transit, such reasonable compensation would soon check the reckless handling on train and car, which, I verily believe, does more to deteriorate the market value of cut flowers and fruits than the entire lack of judgment in packing, of which the Messrs. Draper so seriously complain, and which, I venture to think, they somewhat exaggerate, in order probably to emphasise their valuable advice on the matter.

By the way, there is one point in reference to Roses that seems difficult to understand—that is, that coloured Roses command almost double the prices of white. Some years since, when I consigned Roses to a West-end house, Niphotos commanded superior prices to Maréchal Niel or any other Rose. The chief demand seemed then for

such a pure, shell-like white as *Niphetos*; now the latter yield only 1s. a dozen, while the *Maréchal* and others command 2s. This is very disappointing to those who largely grow *Niphetos* and other white varieties; and it would be of service to growers of *Roses* for sale in winter and spring to have the opinion of the Messrs. Draper on the effect of colour on the prices of *Roses*, and whether the present run of the market is likely to prove durable or permanent.

A NOVICE IN MARKETING.

CHRYSANTHEMUMS.

E. MOLYNEUX.

PLANTS of all sections will by this time be in their summer quarters, and will require daily attention. Those intended to produce large blooms will have been made firm in their position by fixing the stakes securely to the trellis previously described, and will now be all in their flowering pots, and will require constant attention as regards tying the leading shoots. Neglect of this quickly results in the loss of some of the most promising branches, as in most instances the growths, having broken naturally away, are brittle, and easily snap off if tied so tight that the shoot is unable to swell. As the plants are now in active growth numerous side branches will form. These should be removed as quickly as they show themselves, thus diverting all the energies of the plant into the leading or main growths. Green fly will attack the points of the branches in some instances, but dustings with tobacco powder in the morning and a vigorous syringing in the evening will speedily clear the plants of this pest. What is commonly known as the Celery fly will now speedily attack the main leaves. If this pest is not destroyed the plants will receive a severe check. The best remedy is hand-picking, and with the point of a knife break the skin of the leaf at the place where the maggot can be seen, and it then may easily be crushed without doing much damage to the leaves. I have seen plants completely denuded of their foliage for about one-third of their length through not stopping the depredations of this insect. In the case of mildew appearing on any of the leaves apply sulphur to the affected parts. Attend carefully to watering the plants; sometimes in hot, dry weather they will require water at the roots twice every day, and at other times perhaps none will be necessary for two or three days; particularly in this case in dull, foggy weather. Again, after a heavy shower, some people imagine the plants will be wet enough, but oftentimes little of this has reached the roots of the plants, as, owing to the direction in which the wind is blowing or the quantity of foliage some varieties carry, the rain is prevented from reaching the pots, and consequently the plants suffer from dryness. *Chrysanthemums* are generally considered gross feeders; therefore some people think that water applied at any time will do them good. This is a mistake, as *Chrysanthemums* may be spoiled as quickly by giving too much water to the roots as by giving too little. I object to plunging the pots in which the plants are growing, as when plunged the attendant cannot ascertain in showery weather whether water is really required or not. From this time the plants will derive much benefit if the foliage is freely syringed in the evening. This should be no light sprinkling, but a thorough wetting on both sides of the leaves. Where the plants are arranged in rows, no better instrument can be used for this purpose than the garden engine, going down one way, taking each row as you proceed, and returning in the opposite direction. By these means all the leaves

receive a thorough drenching, which greatly assists to keep the plants in health by the removal of many insects which quickly find a footing upon the under sides of the leaves and branches. The plants will now probably require re-labelling. Great care should be exercised in naming all the plants correctly, as mistakes in this often cause confusion, and are very misleading both to the cultivator and to the public. Labels made from builders' laths, cut about 6 inches long, answer well, with a little white paint rubbed on the smooth side previous to using them. The names should be written in a clear, bold hand, allowing space for any remarks to be added.

In the case of specimen and bush plants it is a good plan to plunge the pots half their depth in ashes, as it prevents the roots drying so quickly and keeps the plants steady during rough weather. Where so plunged and for the reasons stated, extra care must be exercised in watering the plants. About the middle of this month the plants intended for specimens should receive their final pinching of the shoots. From the middle to the end of July the branches will be sufficiently long for training to commence. Attend to the pinching and tying out of the shoots on those plants intended for bush specimens, and give the same scrupulous care to watering and keeping them free from insects, as recommended for the tall-growing plants. About this time of the year young growths or suckers will push up from the base of some plants. Where the variety is scarce, and it is considered wise to increase the stock, these sucker cuttings may be taken off and inserted in single pots and placed in a cold frame, where, if shaded and kept close for a time, they will quickly form roots. They may then be shifted into larger pots, placed out of doors, and finally be transferred to 5½-inch pots, allowing them to grow with one stem, which will eventually perfect one flower upon each plant. Such plants as these will be found useful for grouping or standing upon the side stages amongst other plants, as they will vary in height according to the variety. These plants as a rule produce the largest number of cuttings in the autumn and early months of the year, particularly when confined to pots of the size named, and are thus most useful.

Plants growing at the foot of walls are now making rapid progress. Heavy waterings at the roots and vigorous syringings overhead will assist to maintain a clean growth and good leafage, this being of much consideration in this particular method of cultivation.

Ornamental fish-pond.—In reply to "Croydon," in THE GARDEN, June 18 (p. 569), he can have hardy aquatics in abundance to plant in his clay-bottomed pond. We have a similar one, and had much trouble in keeping the water clean until we got it well stocked with plants and fish. For some time the water ran through the pond, but as the supply was subject to ebbs and flows, we diverted its course, and fed the pond by a jet fixed in the middle and supplied from a reservoir at a high level. Before this change, the water flowing through the culvert from an adjacent brook had deposited in the pond a good stock of aquatic plants. Amongst these were the Flowering Rush (*Butomus umbellatus*), the Water Plantain (*Alisma Plantago*), common Arrowhead (*Sagittaria sagittifolia*), American Pond Weed (*Anacharis alsinistrum*) came in, but when the running water was done away with, this plant disappeared, and the *Sagittaria* from the same cause became so weak, that it too seems about to disappear. The only plant in the pond which appears to hold its own, or, I should rather say, more than holds its own, against the vigorous ad-

vance of the Flowering Rush is the white Water Lily (*Nymphaea alba*). A few years ago we threw in three of these, which have grown and thriven most vigorously, maintaining open water all round in which to push their leaves and flowers, the latter abundant. Seedlings of these are coming up all over the pond. Common Duckweed (*Lemna minor*) and *Myosotis* also find a place, and about the edges of the pond some varieties of *Juncus* grow. "Croydon" might introduce to the pond a few golden carp. We have in ours perch, tench, roach, and dace. These all agree, but for the peace of these the freshwater shark had better not be introduced. —WM. MILLER, *Combe Abbey*.

NOTES OF THE WEEK.

ALL the carpet bedding is grabbed up at Blenheim.

Royal Botanic Society.—We understand that the annual evening fête will be held on Thursday, July 7. Prizes are offered for floral decorations, groups, bouquets, &c.

Seedling Petunia.—We have received from Mr. Patrick McKie, Teddington, flowers of a new seedling *Petunia* raised by him. They are of large size and bright rosy pink. It is a variety better adapted for pots than the open border.

Primula Sieboldi is in fine condition at Kew, making a vigorous growth in a sheltered bay on the rockery. There are also sturdy clumps on the mound near the Cumberland Gate entrance, and it is interesting to note the variation in the colouring of the flowers, which ranges from light purplish to the richest crimson.—C.

Aster Stracheyi is a gem for the rock garden. In a ramble round Kew recently we saw a thriving piece on the rockery. It was found on the Himalayas at an altitude of 13,000 feet. It is dwarf, rising but a few inches, and at this season presents a mass of violet flowers as large as those of *Aster Amellus*. It is well adapted for planting between stones.

Royal Horticultural Society's Gardens, Chiswick.—A Strawberry fête, with band and promenade, will be held early in July, date of which will be duly announced. Admission on ordinary days to Fellows and their orders, season ticket holders, and subscribers to the Chiswick Horticultural Society, or bearers of their tickets.

Ornithogalum arabicum.—I have an *Ornithogalum* now in bloom which is new to me, and is most beautiful. It was sent to me in the autumn by Mr. Ware, of Tottenham, as *O. arabicum*. I know very little about this genus of Lilies, and wish to have some information regarding them. —FREDK. CAPEN.

White Pæony and Day Lilies.—We have received flowers of these from Mr. Ware, of Tottenham. The White Pæony (*Pæonia albiflora*) is a single pure white variety, and is described as one of the finest of all the Pæonies. The best of the Day Lilies sent is *Hemerocallis Middendorffiana*, which has large orange-yellow flowers of great beauty.

Blushing Bride Chrysanthemum.—We have received flowers of this excellent summer-blooming variety from Mr. W. Piercy, Forest Hill, S.E., the colour being rosy purple and white. When grown under glass the flowers are larger and of a paler hue. It appears to be a very useful variety, and is well worthy of cultivation for its early blooming qualities.

Jacobæa Lily (*Amaryllis formosissima*).—This is in bloom now, the flowers of bold form and deep red colour. It cannot be accounted thoroughly hardy, but will survive ordinary winters when lightly covered and provided with a warm position. It will do well in a border against a sunny greenhouse wall.—T. W.

Plantain Lilies (*Funkias*) claim attention now by reason of the beauty of their foliage. That of *F. Sieboldi* is very beautiful, and the variegated variety makes a telling feature on the rockery, the leaves being almost white. This may be also grown with advantage as a pot plant, and as such proves useful for the adornment of the greenhouse.—E.

Double and single Pæonies from Messrs. Kelway and Son, Langport, Somerset, are very beautiful in form. We like the singles very much, and are happy to hear that Messrs. Kelway are making a really noble Pæony garden. The purples we do not care much about, but the whites, pale yellow, and pale rose varieties are exquisite. Among the loveliest that have come to us are Afterglow, Pelgams, Josephine, Macella, Iope, Guiding Star, Empress Queen, and Pearl, the last-named a very beautiful pure white.

Allium giganteum.—I send you a bloom of an *Allium*, which I received from Messrs. Ant. Roozeu and Sons, of Haarlem, under the name of *giganteum*. I do not see it in the catalogues, nor in Nicholson's "Dictionary of Gardening." The flower-stem is from 3 feet to 4 feet high.—DELTA.

* A very beautiful thing, with dense heads of small flowers of a pretty lilac colour; the head quite 4 inches in diameter.—ELI.

Dictamnus Fraxinella.—This is the most handsome herbaceous plant now in flower in our rock garden. Its stately spikes stand erect, and are furnished with either pure white flowers or flowers of a pale purplish colour, marked with purplish lines. The hot, dry weather does not in the least affect either flower or leaf. Moreover, the plants do not grow to a great size, which is an advantage to amateurs, as it saves the labour of getting rid of surplus stock.—J. DOUGLAS.

FORT HOUSE, FIFE.

WE like to show views of pretty aspects of country seats in which the beauty results from the simple dignity of trees and Grass, and not unfitting or fussing buildings. We have not the pleasure of knowing this garden, and do not know anyone who knows it, so we put the view in without comment as one of those that reminds us least of the stone-cutter's front garden in the New Road, N.W.

FRUIT GARDEN.

W. COLEMAN.

BLISTER OR CURL IN PEACHES.

MANY fruit growers, those belonging to the old school of hard pruners especially, think there is no remedy for this troublesome disease, but this, I venture to say, is a mistake, for, taking the past twenty

rates; but so long as one or more of these causes remain the disease will be there, the tree will suffer and die or become useless. The north and east winds, no doubt, are enemies which must be guarded against, but badly ripened roots and shoots are at the bottom of the mischief. Twice in my life I have taken to sets of trees badly affected by blister - the last time when I first came to Eastnor. The trees here had been planted in deep, rich borders full of manure; the roots had gone down, gross watery shoots had gone up, and some of the trees were past recovery. My first move, I need not tell those who know me, was lifting, root-pruning, and relaying in pure loam corrected with old lime rubble. The best of them recovered, others were destroyed and replaced with young ones. I then commenced a system of extension training, laying in just enough wood for the succeeding year, and my progress at the end of the first season was satisfactory. All my trees from that time to this (27 years) have been pruned in the autumn, unnailed and washed in January, and kept away from the walls until the swelling buds rendered re-nailing

and spring coping completely cured them. It is now too late for a correspondent, "C. B." (p. 539), who does not give a single clue to his mode of management, to do more than pick off the blistered leaves as they appear, but he may keep the wood thin, the strongest shoots pinched to secure an even distribution of the sap, and point up the borders to let in solar heat. Then, provided these remarks meet his case, experience warrants my saying he may stop the disease by continuing the treatment I have briefly penned for his guidance. For my system in detail I must refer him to back numbers of THE GARDEN, where, under the head "Hardy Fruits," he will find every particular.

MADRESFIELD COURT GRAPE.

BUT for one or two failings, this remarkably handsome Grape would have gradually ousted out the ever popular Black Hamburgh. As it is, we rarely meet with it in quantity, or say to the extent of from six to eight rods in any garden, but nearly

View of the south front, Fort House, Fife. Engraved for THE GARDEN from a photograph.

years, favourable seasons have been few, and yet blister is on the decline. The late Mr. R. Thomson, a hard pruner, thought hand-picking a portion of the affected leaves and protection from cold the best, if not the only remedy, but since his time a great change has been wrought in the management of the roots and branches of Peach trees, and it is to this change, in my opinion, that the improvement is due. Blistering or curling being seldom met with under glass, we have convincing proof its appearance on open walls is produced by cutting draughts, by cold inert borders, into which the badly tended, sluggish roots are allowed to descend, and the injudicious use of the knife, which destroys the balance of the tree by laying the foundation of a few gross watery shoots which never ripen. It is always most troublesome in trying changeable springs when the heat of the wall fluctuates to a great extent, and the roots continue in a slowly changing cold medium. Later on, when the weather becomes settled and the borders warmer, it mode-

necessary. To one wall in a low damp part of the garden I apply glass copings, to another on a higher level broad boards for checking the draught. The roots of every tree are examined, shortened, and relayed in pure loam every year in October, and blister, through good seasons and bad, from that time has disappeared. The copings, I ought to say, are temporary, and are taken away, to let in summer rain and dew, as soon as danger from spring frosts has passed away. For protection two or three thicknesses of herring netting are suspended from the boards, and I water copiously throughout the summer. This season, although the spring has been swallowed up by the winter, I have not seen a single curled or blistered leaf, and the fruit on every tree has required endless thinning. Seven years previous to my coming to Eastnor, I took to a smaller collection of trees in a humid part of Ireland. Their condition was equally unsatisfactory, but complete lifting and replanting in well-drained shallow borders composed of pure loam, extension training,

every cultivator finds a place for one or two Vines, and does his best to bring the fruit to perfection. In some instances the only difficulty experienced is in colouring the berries properly. Others succeed in this respect, but fail to prevent a great proportion of the berries from cracking, which, it is almost needless to add, is one of the worst of all misfortunes connected with Grape growing. If the variety was of comparatively little value, there would be no need to discuss the various methods of culture adopted with more or less success, but as it happens to be both a distinct and, when in good condition, much appreciated variety, no apology is necessary for what I am about to mention. Up to a certain stage no variety of Grape is more easily grown. It is fairly vigorous, but not much inclined to grossness; the wood ripens well, and plenty of bunches are always produced—at least, such is my experience. The berries set as readily as those of Black Hamburgs, swell off a great size, the bunches generally being of good shape, loose, ugly

shoulders rarely forming. If the Vines are rooting in a border formed principally of rather strong loam, the berries are usually extra large and colour readily, sometimes nearly quite up to the footstalk; but in lighter soils a much greater difficulty is experienced in colouring them at all satisfactorily. Unless I am very much mistaken, the failing to colour properly must in most cases be connected with the measures taken to prevent cracking. As a rule, the latter evil is anticipated, or the attempt is made to prevent wholesale cracking by withholding water from the roots, under the impression it is an excess of moisture that causes it. A drier atmosphere and a good circulation of air are also kept up as far as practicable, and the success sometimes attending this treatment naturally leads others to attribute their failure entirely to the neglect of these precautionary measures. What further tends to strengthen growers in the belief that this line of treatment is the only reliable one is the fact that the Madresfield Court, of all Grapes, appears to be least affected by the dryness of the borders. Others besides myself may have seen it perfectly happy in a border so dry as to most injuriously affect Foster's Seedling, Buckland Sweetwater, and other varieties contiguous, these flagging badly on very bright days. I do not say many growers go to the extreme length of long withholding water from the borders of a mixed house of Grapes in order to unduly favour Madresfield Court, but it is done occasionally. The wiser plan to be adopted by the believers in the drying-off theory would be to completely isolate this variety, either by planting at one end of the house and dividing the border, or, better still, by devoting a small house to it. The borders should also be inside if possible, those outside being more at the mercy of the elements, cold and rain. As, however, the majority of the Vines are mixed in with other varieties, very few either dare or care to risk spoiling the latter in order to favour Madresfield Court, and any other successful method of growing would be welcomed accordingly.

In Dorsetshire, more especially in the neighbourhood of Dorchester, there are several good Grape growers, and I have seen both Mrs. Pince and Madresfield Court very fine in that district. At Hsington House, Dorchester, and Froome, Whitfield, the bunches of the latter are invariably very large, plenty of them being from 4 lbs. to 6 lbs. in weight. The Vines are grown in mixed houses, and are found to colour and keep as well as those of Black Hamburgh and Foster's Seedling. On making inquiries as to the liability of the berries to crack, I was assured the percentage requiring timely removal was no larger than in the case of the other sorts. Mr. Powell, the gardener at Hsington House, stated he only had to cut out about six berries, and Mr. Biggs, at Froome, was equally fortunate in this respect. Naturally, I at once attributed their success to the drying-off process, only to find that the very reverse is the case. Instead of this variety requiring less, they hold that it ought to receive much more moisture at the roots than most other sorts, and they act accordingly. When given all they need in the shape of water and liquid manure, the borders never being allowed to become at all dry, the Vines swell off and finish their crops without experiencing a check of any kind, and, as a consequence, the berries are less liable to be suddenly affected by any change in the weather. Those prematurely dried off are bound to receive a check, the skins losing their elasticity, the pulp also becoming somewhat solidified. Then if the border is watered, or a change from clear and dry to sunless and wet weather takes place, a fresh rush of sap to the berries causes them to burst wholesale. This may not be quite the correct solution of the difficulty, but if my physiology is at fault, there is no disputing the fact that those who adopt the plan of drying off very frequently lose a great number of berries, while my Dorchester friends can point to very different results. This being so, it behoves others besides myself to give their plan a fair trial, and if it does not prevent cracking of the berries, it is very certain it will not greatly injure the Vines of other sorts rooting in the same border. In addition, there is a better prospect of the berries being well coloured right up to the footstalks, drying off at the roots

being almost a sure preventive of perfect finish. Madresfield Court forces readily, and can be had nearly or quite as early as Black Hamburgh, but unless it is allowed plenty of time to ripen, it will not often colour well. Give it plenty of time and air, and it will ripen much more satisfactorily than many think possible. W. I.

OUTDOOR FIGS.

"D. T. F.," in THE GARDEN (p. 506), evidently has not honoured me by reading my general remarks upon the management of outdoor Figs; if he has, the thread has slipped his memory, and I venture to think he is hardly in a position to condemn my method or uphold it. Readers who have followed me now for some years will endorse the statement that I am not a coddler, neither do I neglect my trees; consequently his remarks upon a civil inquiry for information which he has converted into a challenge fall short of the mark and are harmless. In reply to his question, I have pleasure in being able to say my trees (Brown Turkey) so far are satisfactory, and as yet the figlets have not fallen to the ground, but shortly some of them will, as they require thinning. But then the weather from the 20th of April down to the end of May was extremely dry, and, although cold, we had nothing like a killing frost to touch the old wood. The figlets were safe enough, for, as usual, I had taken the precaution to remove the winter covering before the sap got into motion. Then even I did not trust to chance or look on with folded hands, for I must remind "D. T. F." that I sometimes fuss about my walls with coping boards and sheets of canvas, which I do not confine to Peaches and Nectarines, but ply wherever they are likely to be of use to me. But, protection. What is it? where does its use end and abuse begin? Protection, I venture to tell "D. T. F." at the onset, with me is not coddling. If he, in his youth, coddled and called it protection, his leap from a prudent course to a let-alone system is by no means surprising. Unnailing the shoots, tying them in bundles, and packing them up like mummies in wheaten straw or air-excluding matting is not protection. Lighter covering, even, put on in the autumn and allowed to remain until the sap is in motion and the young fruit is swelling, is not protection; it is murder; and, as "D. T. F." justly remarks, the mischief follows not the putting on, but the taking off again. My idea of protection is this: The materials should be light, durable, open to a free circulation of air, and capable of drying quickly after snow or rain. They should be fixed firmly, but lightly, not so much to prevent severe frost from entering into the dormant wood at the death of winter as to prevent sudden changes when a thaw sets in and it is coming out again. Many people use Spruce or Yew branches, and very well they answer, but the best material, where it can be obtained, is dry Bracken, to which "D. T. F." I believe, does not object for protecting Tea Roses. This I have used for a great number of years, and when it is borne in mind that a frost which will kill a Tea Rose may cripple a Fig tree, I fail to catch the consistency of protecting the one and neglecting the other. Protection, where is it useful? Figs from the time they were introduced down to the present day have been liable to be killed to the ground, frequently in the midlands, occasionally on the seaboard. Growers in any of the maritime counties, also south of London, may adopt the let-alone system, as Nature, in nine out of ten places, manages better without than with the aid of man. In some few spots away from sea influence trees that have never been pestered with shelter do well, but these isolated cases do not justify the writer of a calendar in saying the Fig is perfectly hardy: all the grower has to do is to put in a tree and leave it to take care of itself. His duty, in my opinion, is to remind growers living in unfavourable localities of their danger. Those who are safe may pass on, as they do not need the warning. Inland, then, the cautious man should use Fern fronds, not to prevent winter frost from getting in, for that is as impossible as it is unnecessary, but to ensure a dry, even temperature when it is

coming out again. Then, for keeping the covering dry, broad coping boards are a host in themselves, as they throw off much snow and rain, and carry the sheets of canvas or fishing nets, which I use and recommend, from the time the dormant figlets are unfurled until danger from spring frosts has passed away. I do not request anyone to follow in my footsteps. I do not ridicule those who differ with me. I merely preach what I practise, and having been fairly successful with Figs, as well as other fruit, I leave readers of THE GARDEN to accept or reject matter which may or may not suit them. W. COLEMAN.

Strawberry plants as biennials.—Generally, forced Strawberry plants are so treated because of the large number of plants grown, but a small number are planted out to form permanent beds. On the other hand, we invariably treat outdoor Strawberries as perennials, and although they are assumed to have a limit to useful endurance, yet they will endure if left indefinitely. But there is no good reason why we may not treat outdoor Strawberries as biennials, planting them thickly, as advised by others. I have in past years taken fine crops from plants so treated, and then have dug them in to make room for something else. Several hundreds of stout, early runners dibbled into 4-foot beds thickly will give, the following spring, a remarkably fine lot of fruit with the least possible trouble, for mulching is not desirable and top-dressings are not required. An arrangement of this kind would be very acceptable for small gardens, and if the plants were dug in as soon as the fruit was gathered, Broccoli would follow admirably as an after crop. One hundred plants in a row specially planted, and having the flowers pinched out, would suffice to give runners for the ensuing season. I recently saw a lot of plants lifted from a bed of this description in the month of March, and planted a foot apart each way in frames moderately close to the glass, which had produced so much bloom, that one-half of it had been thinned out. A really fine crop of fruit was taken from the plants in succession to those in pots.—A. D.

Strawberry beds.—It is now being realised how much hardier and more prolific young Strawberry plants are than old ones. We have, for several years, grown beds of runners on two different systems, a few remarks upon which may prove serviceable. It is customary here to plant a row on each side of a bed 5 feet wide, and from the space between the rows runners are taken. Those layered after the first two or three batches have been removed are allowed to remain, care being taken that they are not crowded, and a most prolific crop will result the following summer. There are, however, some disadvantages in this system. The first is the uselessness of the bed after the fruit has been gathered, for if left until another year the growth of the plants blocks out the light and air necessary for the ripening of a second crop. When layered close even the first crop will be greatly deficient in colour and flavour. Dry seasons will likewise do much mischief to a bed, the ground being so thickly matted with roots, and watering in such cases has a tendency to draw the leaves and destroy the quality of the fruit. Great exhaustion, too, of the soil follows a bed of this description, which makes it all the more necessary that the bed should be destroyed after the first year. However, judgment exercised in the layering, followed by good cultivation, will seldom fail to yield one magnificent crop. The other method is simply a transplanting of the runners to a 3-foot, 4-foot, or 5-foot bed in rows from 1 foot to 1½ feet apart, the plants being placed 6 inches from each other. The outsides of the bed must be well littered with straw; the trusses inside will be held up by the foliage. A light mulch, however, previous to blooming is helpful, more especially in the wide rows. In the second year every alternate row should be removed and the space dug and mulched. It may be also better with the more vigorous kinds to remove every alternate plant, and so give ample room for the development of the crowns. We have

had some of the finest fruits, and also some of the earliest, from beds treated in this manner. J. LOVELL, *Driffield*.

THINNING APPLES.

ALTHOUGH the thinning of Apples is not generally practised, there is no doubt that they are just as much benefited by the operation as any other crop, and will repay the extra labour involved, just as well as Grapes, Peaches, or any of what are termed choice fruits. I do not suppose that the thinning by hand of large orchard trees will ever be generally practised, but I consider it advisable to go over all dwarf or trained trees just after the flowers fade, and thin out the bunches to one, two, or three of the best fruits, according to strength of tree or the size the variety attains, as half the number of Warner's King will tax the energies of the tree to swell them out to full size more than double the number of Golden Pippins, or any of the small dessert kinds. In addition to this there is a great advantage in removing the old blossoms, as they harbour grubs that eat into the young fruits, which, once blighted, never grow into fine clear specimens. There is generally plenty of small common Apples to be had at low prices, but what growers want to obtain is a fine sample that is fit to be sold at so much each or per dozen. The demand is for large culinary Apples for baking whole and various other purposes. One of the kinds that is in great request is Lord Suffield. It is such a fine cropper that it needs thinning out early, and then it attains a large size, and no Apple that I know of pays better as an early variety. Then there are such varieties as Winter Hawthornden, Warner's King, Lord Derby, Blenheim Orange, Ribston Pippin, Cox's Orange, and many other popular sorts that are grown in quantity for market that pay far better than Grapes do now-a-days for any attention that may be bestowed on them. Anyone making a speciality of some of these leading kinds would never regret any outlay to produce the best samples that could be had. They must be grown on some kind of dwarf tree, and the finest I have ever met with have been grown on cordons, and many Peach, Plum, and other fruit trees that do not yield satisfactory returns would, if rooted up and replaced with good Apple trees trained and carefully attended to, yield not only regular, but far more profitable crops. It is thought by many useless to plant Apples on walls because they can be grown in the extreme north of these islands; but if the question is profit, it matters little what the crop is. And in the extreme south I have seen Apple trees on walls, year after year, never fail to yield a crop that for value was equal to that of any other wall trees in the garden; and if one cannot devote walls to their cultivation, he can at least give the requisite culture to ensure fine crops. J. GROOM.

Gosport.

SEASONABLE WORK AMONG FRUITS.

CHERRIES.

EARLY houses in which ripe fruit is still hanging cannot be kept too cool and airy; also they must be kept dry, but not to an extent that will conduce to premature shrivelling. When the trellis is completely furnished with foliage, the best of all shading, and the floors are kept cool and moist by daily sprinkling, the most tender varieties will keep for a long time; but where the leaves are thinly placed, a sheet of canvas drawn over the roof will now be found necessary. Some Cherry forcers allow this shade to remain night and day, but, provided each end of the house can be reached, shade when the sun is not shining should be removed, otherwise the foliage becomes tender and often ripens prematurely. Birds, of course, must be kept at a respectable distance by means of strong netting; the roots must be kept evenly moist beneath the mulching, and the foliage as the trees are cleared free from insects by a vigorous use of the syringe. As early-forced trees are more likely to get too forward than otherwise, it is not necessary to keep the glass over them after the latest sorts are gathered; therefore, provided the lights are portable, their removal will

tend to the preservation of the foliage by the aid of rain and dew through the most trying part of the summer. On the same grounds, pot trees, unless they require a shift, when retention for a time may be necessary, will do best plunged to their rims and well mulched on an open border. The pots being very full of roots, they will take liberal supplies of water, as the heaviest summer rains rarely pass through the leaf-shaded balls, and the garden engine, after a hot day, will cleanse and refresh the foliage.

Late houses, containing the best of the Bigarreaus, need not be closed through the night, neither need much, if any, shade be used, as this valuable section cannot be properly coloured without the assistance of sun-heat and an abundance of light. When properly finished, the damping, as recommended for the early house, must be repeated on a more liberal scale, and more air, if possible, will be found a telling factor, always provided the rain does not enter through the open roof-ventilators. This family of Cherries are a host in themselves, but unfortunately, in this part of the country, they are rarely met with in perfection on open walls, and when they do ripen, wet, sudden changes, birds and insects rapidly destroy or reduce their numbers. In low, cold, and damp districts their culture is more trying and precarious than that of Peaches, and for this reason it is to be regretted that more glass is not devoted to them. A light, airy house, of the plainest build, is all that is needed, and although a handful of fuel is a saving agent when the trees are in flower, not so much from frost as from damp, excellent fruit can be grown in eight seasons out of ten without it.

PLUMS.

Trees in pots now swelling off full crops of fruit will take frequent supplies of diluted liquid and good top-dressings of a rich calcareous nature. Well rotted manure, freed from worms by a dash of soot, forces a vigorous growth of wood and foliage, but the finest and best fruit is produced by stiff loam, fine lime rubble, and bone-dust. This we lay loosely on the surface, wash in with liquid, and replenish as soon as the roots appear on the surface. In course of time the dressing rises above the rims of the pots, but this difficulty is met by the introduction of narrow hoops of zinc or lead, some 3 inches in depth, to facilitate our giving abundant supplies of water. The sudden change from winter to summer will necessitate a most vigorous use of the syringe—the first time, as soon as the doors are opened, the second, after the trees have been watered, and the ventilators closed for the evening. The Plum, like the Peach, being so easily marred by impure water, constant attention to the selection of this element is imperative. That which falls from the clouds, of course, is best for the trees and the fruit, as it can be used until the Plums begin to colour. This stage reached, an abundance of atmospheric moisture, produced by damping the floors, walls, and stems, will ensure perfect bloom, and keep the foliage free from spider. If any of the earliest trees have missed fruiting, they will now be sufficiently advanced to admit of being passed through the cold house to the open air, where they will set and ripen their buds in time for next year's forcing, whilst those left will get more light and air—important factors in Plum forcing.

Late sorts, including Golden Drop, the Impéatrices, and Rivers' Late, a variety not half enough grown, in succession houses will now be forward enough for the final thinning. Quality being preferable to quantity, the Grape scissors must be freely used, also the finger and thumb, as full size cannot be obtained where the trees are allowed to run into strong laterals. Once thinned and swelling freely, the latest sorts do not require fire or hard forcing with solar heat, but thrive best under a liberal circulation of fresh air from early morning until the time arrives for the evening syringing.

MELONS.

Plants in all situations and stages with a minimum of fire-heat are now making a maximum of growth, and show, by their deep green, leathery foliage and highly coloured fruit how they revel in

bright unclouded sunshine. Where the fruit is passing through the setting stage, an abundance of air and plenty of atmospheric moisture will produce safe and favourable conditions, always provided the bottom heat is satisfactory. Good Melons, no doubt, are often grown upon a low bottom heat; but time is money, and one bright period does not make a brilliant summer; therefore, a root temperature corresponding with that of the air must be maintained by the renovation of the fermenting material in preference to dry and more costly fire-heat. Where the pot system is still in favour, fresh, free, and vigorous plants should always be coming on for filling up the compartments as they become vacant. A two-light frame resting on a manure bed is the best of all nurseries, as clean, stocky plants in these can be raised in endless quantity. A few seeds sown every week singly in pots, or, better still, on small squares of turf, is the best safeguard against the disappointment which follows the use of plants that are drawn, pot-bound, or touched with spider. Extension training is a system well worth the attention of Melon growers who have good-sized houses. I once saw the Melons grown in this way at Longleat, and certainly they were magnificent. Mr. Pratt, I gather, follows in his predecessor's footsteps, and worthily he wears his mantle.

Frames.—It is not yet too late to put out strong plants in pits and frames where the grower is solely dependent upon manure for top and bottom-heat. Indeed, there are many gardens in which frame culture is not attempted until after forced vegetables and bedding plants are disposed of. Old beds containing some latent heat may be revived by turning and the addition of a little fresh fermenting material both inside and to the external linings. The soil for frame Melons should be sound, mellow, calcareous loam that will grow good Strawberries or Roses—not too rich, but good enough to produce healthy plants without the aid of manure. Lime rubble or burnt earth, however, may be added; the first to all soils; the latter to stiff or poorer loam of a clayey nature. If the compost at this season is spread out in the sun for a few hours, the hills or ridges may be made and planted almost immediately, but this will depend upon the condition of the plants, which should grow from the seed to the fruit without undergoing a single check. It is well to raise the stems a little above the general level of the hills; and whilst keeping the plants well up to the glass, they should have room for the full development of the foliage without touching it. When stopped, and the young vines (two to four from each plant) are growing freely, airing should keep the temperature at or about 85° under bright sun, which cannot be too hot for Melons; and nights being cold, early closing with the tepid bath should be finished in time for the afternoon heat to range from 95° to 90°. When growing plants are shut up with a frame well filled with vapour, there is no fear of scalding, although the temperature touch 100°, but under this high pressure night chills must be guarded against by early covering. The small volume of heated air passes quickly away after the sun leaves the glass, but the days being very hot, this important operation of early covering is often neglected. When new beds are made up for late Melons, it is a good plan to economise material by building upon a double row of fagots, as there is then less danger of delay or burning; whilst the hollow nature of the base is favourable to an under-current of heat when the linings are renovated.

CUCUMBERS.

These in frames, like Melons, require a free, but not over-rich soil, a steady bottom-heat, plenty of tepid water, and the early afternoon bath with strong sun to ensure a quick growth during the hours of declining daylight. Frame Cucumbers require stopping and regulating three times a week and keeping evenly balanced with foliage. The best time to dress the plants is the half hour preceding closing, as one exposure will then suffice for this work and the overhead watering. In course of time it may be necessary to cut over a few lights of plants, and peg down at the joints a few of the leading shoots to induce the formation of fresh rootlets. When trimmed and pegged, a light top-

dressing of fresh maiden soil, leaf-mould, and lim rubble will give them a new lease, and the plant will go on bearing until the remainder, so treated in their turn, come into bearing.

Cucumbers in heated houses just now are growing and fruiting freely under the influence of solar heat by day, and a gentle circulation on the pipes through the night. Of tepid water the roots will take an enormous quantity, and if one so wills it, the Vines will luxuriate in a close house filled with vapour and fully exposed to the brightest sunshine. I do not, however, adopt this plan, and although I never shade, I ventilate moderately through the early part of the day and close about 3 p.m. with moisture on the hottest afternoons. By adopting this method and pinching at the joint beyond the show, the growth does not become lanky and untidy, insects do not make headway, and the fruit is straight and never bitter. A very common mistake in house culture is close planting and crowded training; the plants go on well for a time, but soon become debilitated by the knife and get out of health and order. If anyone doubts this, let him turn out a single plant where it can have an unlimited leaf-run and he will soon find how fruitful it is, and, comparatively speaking, easily managed. To those who are suffering from overcrowding, I venture to say, cut out every alternate plant, when those left will give less trouble, produce finer fruit, and more of it. Extension-trained Cucumbers require a liberal root-run, not in a rich, declining bed of leaf-mould, but in sound, well-drained loam, through which the liquid passes quickly. Of this the roots take large quantities and follow it through the drainage, always provided it cannot remain to become stagnant. Top-dressing, little and often, in like manner must be liberal. The best material I have used is rough, turfy loam and old lime rubble; indeed, the latter, I believe alone, well fed with warm liquid, would grow the plants for an indefinite time, and worms—the great bane where manure is used—would never enter it.

PEACHES.

By this time many early houses will have been cleared of the fruit, and having the hottest part of the summer before them, the most careful management must be devoted to the trees. When with the hose or garden engine the trees have been thoroughly cleansed and the roots properly moistened, all shoots that have performed their allotted work must be cut out to let in light and air, without which the foliage will ripen prematurely, and the hard, brown wood studded with bright flower-buds will be represented by pale green shoots sparsely furnished and greatly elongated. The worst enemy is red spider, which attacks the upper as well as the under sides of the leaves during the time the fruit is ripening, but a few thorough washings with pure water will break up its stronghold, and continuous syringing late in the evening whilst keeping the foliage cool will prevent its reappearance. Old trees from which heavy crops have been gathered will most likely require gentle stimulants in the form of manure mulches and diluted liquid, but feeding must not be carried to excess, otherwise a persistent growth of lateral will be found troublesome, if not injurious, when they should be resting. Although all early Peach houses should have movable roofs, the old-fashioned system of stripping should not be thought of until the wood is thoroughly ripe; then, provided the latter part of the summer is hot and dry, the lights may be taken in for repairs and painting. Meantime, the lights must be run up and down to their fullest extent, not only to ensure a full current of air, but also to give the foliage the benefit of dew and rain.

Succession houses.—The weather since June set in has been almost too hot and forcing, but where ventilation is on a liberal scale the fruit has coloured perfectly, and fire-heat, of which they have had more than enough, has been dispensed with. Plenty of water above and below and a free circulation of air are the principal elements, as size and flavour cannot be secured without their aid, and colour depends upon the elevation of the fruit to the light. Lately we have thrown the lights completely off our colouring Peaches for a few hours

during the hottest part of the day, and then the thermometer beneath the foliage has stood above 80°. Nights, however, have been cold, often showing a fall of 40°; therefore, the better to dispense with fires and ensure full size, we have closed pretty early with sun-heat and moisture. If young trees are still growing freely, they should be tied in as the shoots extend, stopping only being resorted to where the strongest are taking the lead or have reached the extremity of the trellis. If likely to become crowded, many of the minor shoots which will be cut out when the fruit is gathered may be pinched a few inches in advance, for the two-fold purpose of increasing its size and letting in light and air.

Late houses may now receive the final thinning, the crop being regulated by the vigour of the trees. The strongest, however, should not be over-loaded, as the ordeal of stoning is still before them, and it is better to secure a moderate crop every year than to enervate the trees with inferior quality and suffer for it in the future. Growth being unusually rapid, the tying and regulating of the shoots, especially of the strongest, must receive frequent attention. The trees having been freely disbudded to a sufficient number of shoots, tying in is a simple operation, as there is no difficulty in finding a place for every growth, but when young hands have to follow an inexperienced disbudder, the work becomes tedious and the trees suffer. If this hot, dry weather continues, more mulching followed by copious watering will tell in the right direction upon external borders, and those inside will take a flooding every ten days. Where very late fruit from this structure is wanted, now is the best time to retard by abundant ventilation, which in many ways answers better than shading later on. In the first place, the free admission of light and air lays the foundation of a short-jointed set of shoots, which invariably ripen well. In the second, high colour and flavour are ensured by full exposure to sun and air when solar heat is declining; and last, but not least important, a glut of shaded overripe fruit is avoided.

W. C.

FLOWER GARDEN.

BEAR'S-EAR SANICLE.

(*CORTUSA MATTHIOLI*)

FROM the old garden type, well represented in the annexed cut, to the larger Himalayan variety of this plant, the improvement is very won-

Bear's ear Sanicle (*Cortusa Matthioli*).

derful. There are several intermediate forms which we have seen in cultivation lately. *C. M. grandiflora* is a large-flowered form sent out a few years ago, we believe, by Herr Max Leichtlin, of Baden-Baden, and is now a general favourite; it is really a most handsome flower at this season when well grown; the leaves resemble the old form, as also do the flowers in colour, but they are twice the size, and very pretty when seen in a mass. Another form from the Himalayas has flowers even larger and paler than those of *C. M. grandiflora*, and the leaves, in-

stead of being shiny and almost devoid of hairs, are quite soft and velvety. A very dwarf form also comes from the above locality, with numerous flowers on a short stalk, almost identical in colour with the old double Peony. It seems to be the rarest of all. As seed ripens freely, I find the best way to treat these plants is as biennials.

K.

Double Wallflowers.—I have now in flower three forms of the old-fashioned double Wallflowers—not the large, ungainly double German varieties—two of these are yellow and one dark. Of the yellows, one, the earliest to flower, is quite pure in colour, buds and flowers alike being destitute of any dark stains whatever. The other yellow is later in flowering; the buds are dark until the flowers expand fully. They are bright yellow, large and full, and form massive spikes. Of this I have a dark counterpart, the same in all respects, but the flowers are dark, and not so black as they are in the case of the old double black, which is a counterpart of the early pure yellow, only varying in colour. The old dark I have unfortunately lost. How many varieties of the old type of double Wallflower are there? I mean, of course, the free-flowering forms that are met with in old-fashioned gardens. They possess one excellent quality—they last a long time in flower. I shall be glad to exchange cuttings of either of these for the old double black which I have lost.—R. D.

Brompton and other Stocks.—In spite of the severity of the winter, a few of the winter Stocks here and there have stood very well, and notably the robust, bushy Queens, the hardiest strain of Stocks we have. I meet with plants here and there in cottage gardens of the white and purple kinds, but the scarlet seems to be rarer, perhaps because more tender, or perhaps the Stock is less common in this locality. These bushy branching Stocks are very sweet, very free flowering, and furnish ample material for cutting, if it is desired. The only Brompton Stocks I have now were kept in pots in a cool house during the winter. The plan gives much trouble, and can hardly pay, as the plants must be kept in 1½-in. pots at least, and in these they get somewhat root-bound before it is safe to turn them out. I had sent me a small packet of seed, said to be of a very fine strain, and through that, out of the couple of dozen or so of plants I had, was enabled to find that there is an inferior strain of so-called Brompton Stocks in commerce; hence the appellation of Giant to the large-flowered strains. The inferior strain produces flowers pale of hue, and are chiefly produced on side stems, there being no really good spike. I rather think it is the Emperor of the Continent which is thus sold for the scarlet Brompton, and a very poor substitute it is. I hope we may have some milder winters, that we can again enjoy in all their grand beauty fine scarlet and white Brompton Stocks.—A. D.

Verbenas and Calceolarias.—To judge from the instructions on the summer preparation of beds for the above flowers occasionally given in the weekly papers, the idea still seems to prevail that they require plenty of manure. Is the poor appearance and gradual decline in public favour of both Verbena and Calceolaria, that have come about within the last few years, to be attributed to the fact that the above instructions still find favour with cultivators? There is not the slightest doubt that anything in the shape of raw manure dug into the beds immediately before planting is highly injurious to them, and I can well remember repeated failures with the Calceolaria in an otherwise perfect garden, where the manure and firm planting were essential features in its management. So far as Verbenas are concerned, I have always found them do best in a sandy loam, and where this is not natural to the flower garden the desired end can be attained by working into the beds at planting time a good dressing, say 2 inches or 3 inches in thickness, of road scrapings, obtained from a heap that has been turned once or twice, and if good sturdy plants are turned out in this compost the beds will be quickly covered and

bright with colour. One particular point to be observed in the spring management of Verbenas is that they should be kept growing until wanted for the flower garden. If struck early and allowed to stand in cutting pots until the end of May the plants are crippled, and will not establish themselves in their summer quarters until the season is well advanced. I generally strike them about the last week in March, shift the pots into a cool frame for a week as soon as the cuttings are rooted, and then plant them out in pits that have been used for forcing Potatoes. With this treatment they make nice plants by the end of May, come up with good balls of earth, and do not feel the removal. With respect to Calceolarias, I have found a mixture of leaf-soil and road sand in the proportion of two to one a capital compost to work into any beds that are to be occupied with these flowers, the natural soil being removed either in large or small quantities as may be deemed necessary. They may be planted firmly in this compost, and a slight treading given to the beds when the planting is finished.—E. BURRELL.

RAISING ALPINE RANUNCULI FROM SEED.

THESE may be raised from seed, and strong specimens obtained in a short time by a most simple, though perhaps a little unusual process. I am now referring to such kinds as *Ranunculus anemonioides*, *parnassifolius*, *amplexicaulis*, *glacialis*, *montanus*, *magellensis*, *alpestris*, *Trautffelleri*, and *gramineus*. It is just a year since I sowed the seeds, and the plants are now neat little tufts, some of which for further increase I have just been dividing. The plan is to take the whole head of seeds just as the neck of the flower-stalk begins to turn brown; about this time many will be nearly ready. The seeds may appear rather green, but if they are otherwise good, no matter. Set the whole heads just as you cut them from the stalks, and in the same position as when on the plant. Cover to the depth of half an inch in grit, peat, and loam; plunge the seed pots to half their depth in ashes in the full sun, and do not water them. The results, according to my experience, have been that in one year I have crowded clusters of seedlings, which as regards the smaller species might almost be taken for old plants, and in all cases they can be readily divided. My practice has long been to grow Ranunculi in nearly single crowns, in order to obtain fine flowers, but I have not yet found a means nearly so handy for raising them as by perfectly fresh seeds in the clustered heads. I took the hint from noticing that the seed heads often left the plant by the old flower-stalk decaying, and from seeing that seedlings came up in corresponding tufts in the autumn. So much for the facts; and one may fairly suppose that the condition of the soil at this season is more suitable for the seeds of this genus, wherein at the same time they can ripen, keep plump, and conveniently get rid of their husks at the right time. I wonder if the seeds of R. Lyalli were cut off the plants in a corresponding fashion, and sent without being dressed at all, we should manage to get them to germinate better than hitherto. I should be most happy to try them if procurable. I have never yet, by the ordinary plan, got a seed to vegetate out of all the packets I have bought. J. WOOD.

Woodville, Kirkstall.

Libertia ixioides.—This plant, with its tuft of Iris-like leaves and profusion of small white blossoms crowded together on spikes about a foot high, not only does well in an open sheltered position, but may also be grown in pots, and if wintered in a frame will be by now bristling with flower-spikes. In this condition it is very useful for the decoration of the greenhouse, and is also very distinct from the plants usually grown for that purpose.—H. P.

Hoop-petticoat Daffodil (*Narcissus Bulbocodium*).—This is a lovely gem, valuable both for pots and the open ground. It is as a border plant that I wish to recommend it, as it is of easy culture, thriving in almost any soil and situation. It in-

creases fast, and some clumps here have produced upwards of 100 flowers. As a plant to cut from, it stands in the foremost rank, and its simple, elegant appearance merits attention. This and the Pheasant's-eye Narciss mingled with the old double white make a pleasing combination, and give as much pleasure as many other things grown at double the cost.—J. CROOK, *Hants.*

POPPIES.

THE Poppy, in some of its various forms, has long been grown in gardens, and, in our opinion, no really good collection of hardy flowers is replete without a selection from this charming genus. From the dwarf Alpine Poppy (*P. alpinum*) to the majestic Opium Poppy (*P. somniferum*), with its gorgeous colours, the range of form, &c., is very great. The latter Poppy is only an annual, but of such a nature as to require very little attention in the way of sowing, &c., in our climate, unless in very severe seasons. It displays an almost endless variety in the shape, colour, and form of the flowers, some of them more resembling the individual blooms of a Hollyhock than anything else. The type, *P. Rhæas*, is a native of

A Japanese Poppy (*Papaver Rhæas* var. *japonicum*).

our own country, and grows wild in cornfields, &c. The variety *japonicum* (represented in the annexed cut) and the variety *Hookeri* show what may be done by cultivating our native plants in foreign countries. The variety *japonicum* is cultivated in gardens in China and Japan, and forms one of the most charming and striking plants that can well be seen in any garden. The variety *Hookeri*, cultivated in gardens in Cashmere, on its first introduction appeared distinct, though after cultivation it showed a decided tendency to revert to the type. Many of the French varieties are also very handsome, and all are allied to this species. The form *umbrosum* is very distinct, as also is *Danebrog* and many others without distinctive names. The Iceland Poppies (*P. nudicaule*), so easily raised from seed, should be largely grown in every garden. When grown in a rich soil, the yellow and rich orange-white and streaked flowers give one of the most gorgeous displays that can well be conceived. K.

Veronica Hulkeana in Ireland.—The editor (p. 527) asks me for a note as to how this grows in Ireland. So far as I can learn, it is whimsical. Here it grows freely, and as the specimen sent, I think,

shows, blooms well; plants against a wall and growing in a gravel walk are sheets of blossom every year. It also flowers well in the open, but growth is less compact. Elsewhere, I am informed, it is found difficult to grow. I believe neither Miss Owen nor Mr. Gumbleton have been successful with it. It does well in the Trinity College Garden, but, I think, is almost better here. Perhaps soil may in part account for the variations. Mine is a heavy tenacious clay, baking in summer as hard as a road. Miss Owen's is light and sandy; Mr. Gumbleton's I do not know. V. Lyalli also does well with me.—GREENWOOD PIM, *Monkstown, Dublin.*

TULIPS.*

THE Tulip derives its name from the Persian word *Thoulyban*, turban, the eastern headdress much worn in Turkey, Persia, and other eastern countries. In Turkey the Tulip is named *Tahilant*, also because of its resemblance in shape to the headdress there in use. From a book published in the Dutch language, printed in Antwerp in the year 1614 by Rembertus Dodonius, a botanist at that time, it is mentioned that the Tulip in former ages was known by the name of Pythion, and at that time the wild Tulip was eaten and was used for thickening the milk. Theophrastes, another author of past ages, declares the Tulip to be very good food, while two other authors, Hesperidius and Gesner, in their botanical works, mention that the old name was *Satyrium Erythronium*, which was considered at that time a very good eatable bulb.

HISTORY.—Mr. Corn. Gesner, called the Linnaeus of the 16th century, met with the first Tulip at Augsburg (Germany), in a garden of which the Councillor Johan Heinrich Herwart was the proprietor. It further appears that the first Tulips were imported into Holland in the year 1522 by M. Augerius Gislennius, of Busbeec, born at Commines, in French Flanders, and died at St. Germain, near Rouen, on October 28, 1592, which gentleman had been sent out by the Emperor Frederick the First to Soliman the Second to Constantinople. This gentleman, having travelled through a good portion of Asia, brought the Tulip to Holland, having collected it in Persia. The first Tulip was seen in bloom in Amsterdam, where it was greatly admired by the public, but Carolus Clusius, a botanist at Utrecht, was the first who occupied himself with the growing and distributing of the Tulips. This gentleman distributed the Tulips all over Holland, and created a taste for them among the public, which led at the time to the neglect of all other flowers. At that time the Tulips were sold at pretty high prices, although not equal to the prices in the speculative days later on. *Tulipa Gesneriana*, brilliant scarlet with black centre, is probably the mother Tulip from which all the many hundreds of different varieties have originated in almost every shade of colour, from pure white to the darkest crimson. This sort is an importation from Asia Minor, the Caucasus, Calabria, and Central Italy. M. Conrad Gesner, a Swiss naturalist in whose honour it was named, mentioned this Tulip first, and published a description of the same, accompanied by a drawing, in 1559. He obtained it first in a garden at Augsburg, where it had been grown from seed brought there from Constantinople. It was first flowered in England by Mr. James Garres, an apothecary, in 1577.

The character of a good Tulip consists in the novelty of the sort and in its peculiar markings, either feathered or blotched, with a pureness at its interior base. The ground colour should be clear and distinct, whether white or yellow. The petals should be of firm substance, not withering soon by the action of the sun, but keeping their true colouring for at least ten to fourteen days. These late or fancy Tulips, which have been so much admired by many generations, have been grown from seed by thousands, and the result of this has been the acqui-

* Abridgement of a paper read by Mr. Polman Mooy, of Haarlem, Holland, at a meeting of the Horticultural Club June 14, 1887.

sition of many superb varieties, at first in Holland and Belgium and later on also in England. The seedlings generally, when they first bloom, produce flowers without any stripes or markings, but with a yellow base, the upright portion of the petals being self-coloured brown, red, purple, scarlet, or rose. In this state, when they have been grown for years without variation, they are called breeders or mother Tulips. These are planted every year until they break into stripes, when, if the markings are fine or different from any one known, they receive names, and are added to the collection. It is often so many years before they break, and the multiplication in the breeder state is so rapid, that the border soon becomes filled with this self-coloured variety. Each Tulip grower who has broken seedlings claims, and has a perfect right, to give each flower a name; but some confusion is naturally brought on, because of the fact that different names have been given to those that have broken almost exactly alike. In a bed of 100 seedlings it is improbable that any two will be very nearly alike in their markings, which uncertainty adds greatly to the charms of Tulip cultivation. Another singular feature in the Tulip is that after it breaks it ever remains the same, and never returns to its self-colour again.

SHOW OR FANCY TULIPS are divided into three classes: 1st. Byblomen or violets, such as have a white ground variegated with purple or violet, the edges well feathered, the leaflets erect, and the whole forming a perfect cup. 2nd. Bizarres having a yellow ground variegated with rose, scarlet, purple, or violet. 3rd. Roses with white ground colour variegated with rosy red, pink, or soft rose.

THE PARROT TULIPS are well worth our attention. We cannot say for certain where they originated, but I am of opinion that they were derived from a monstrous sport out of the late or fancy Tulips, among which they are occasionally found. They may be ignored by those florists who claim the right to say what is and what is not beautiful, but I prize this class very highly on account of their singular picturesque appearance, and their large and exceedingly brilliant colours; while it is a fact that the demand for them from all quarters is very considerable, and has been increasing of late. They are unequalled for groups in mixed borders or conspicuous places in front of shrubs, and they also prove very ornamental if planted in hanging baskets or other hanging ornaments. The variety in this class is very limited, their colours ranging between deep red and pure yellow, but they are, nevertheless, beautiful and attractive, and more particularly so those of decided colours, such as rubro major, luteo major, &c. Besides these classes of Tulips which I have mentioned and described, there are some sorts which are grown and sold under the name of botanical Tulips, because they do not quite belong to the classes I have spoken of, but which are desirable for their particular property and beauty. *Tulipa Clusiana*, a small miniature Tulip; very beautiful. *T. florentina*, yellow, and very sweet-scented. *T. Oculus solis*, crimson, with dark bottom. *T. persica* or *Breyiana*, fragrant yellow; small flower, and very dwarf and neat. *T. Eichleri*, orange; of recent introduction. *T. Greigi*, light orange, with blotched foliage; also of recent introduction. *T. Haageri*, red. In the botanical works are found several more names of Tulips which are not in general cultivation, probably because they do not attract the eyes of florists by their beauty or other properties.

CULTURE OF THE TULIP.—The best soil is a rich, rather light, well-drained sandy loam. A bed of sufficient size for planting the bulbs should be dug at least 12 inches or 14 inches deep. The Tulips should then be planted 4 inches apart each way, pressed deep enough to keep them in their places and covered to the depth of 3 inches on the sides of the bed and 5 inches in the centre. This precaution is necessary so that water may not stand on the bed during the winter. When the bed is planted and covered, it may be left to the weather until the Tulips come up, or about March 1. A slight protection of litter is then required, as the frost, if severe, has a tendency to check the bloom. Our climate is so variable that it will be well to cover at night and remove in the morning; but if

the foliage is left for a long time covered up it has a tendency to become drawn, and thus weaken the plant.

When the flowers are protected from the sun by a light canvas, the period of bloom may be kept up for three or four weeks. The colours are generally better if not shaded at all, but in that case the bloom, particularly in hot weather, would soon be over. Sometimes a single day's hot sun will completely spoil them. When the flowers begin to fade they should be cut away. Never plant Tulips in the same bed, or rather in the very same soil, for two or three consecutive seasons, or if such cannot be avoided, take at least 2 feet of the old soil out of the bed and replace by fresh material. If this is not done the Tulips will bloom less satisfactorily every year, and at last not bloom at all. I know that very often this has been the cause of great disappointment to buyers, who blame, although erroneously, the seedsmen or the grower who has supplied them.

HERBACEOUS PÆONIES.

IN THE GARDEN, June 1 (pp. 512, 513), "D. K." describes certain herbaceous Pæonies. With several of his remarks and classification I do not agree. I will first deal with his classification. *Pæonia officinalis lobata*, so called by Mr. Baker in his able and much-needed monograph, "D. K." sets up as a species, and says it is perfectly distinct as a garden plant. It is certainly distinct enough, and is also one of the most beautiful of Pæonies, but still it is only, in my opinion, a variety of *officinalis*, as all well acquainted with it will admit. Now, as regards "D. K.'s" remarks, he gives *P. officinalis*, the type, and *P. o. anemonæflora* as if they were two constantly distinct forms. At one time this I should have considered correct, but latterly I find that the flowers of the typical *officinalis*, when the plants are grown well, assume more of a double form (hence the name *anemonæflora*), but as soon as the soil in which the plants are growing gets exhausted, the flowers gradually appear in their normal characters. *P. o. albicans*, the type, "D. K." says, is not so free as *P. officinalis fl.-pl.* With me it grows quite as freely, but the flowers are scarcely so large. *P. o. blanda*, "D. K." says, "flower-stems reddish." This is rather misleading to individuals who wish to identify their own plants. *P. o. blanda*, as far as I am acquainted with it, has a perfectly light green stem, as "D. K." will find on again looking at his specimen—at any rate if his plant is in a thoroughly healthy state. *P. o. carnescens fl.-pl.* "D. K." speaks of as having been first recorded by Morrison about 1699; this I know nothing to the contrary about, but under the above name and also the following five, viz., double pink, double rose, both from one source, *incarnata fl.-pl.*, *mutabilis*, and *rosea fl.-pl.* Under all these names I find this one form, which corresponds in colour to one in the Botanic Gardens, Oxford, under the name of *P. officinalis rosea fl.-pl.* *P. officinalis Sabini*, "D. K." says, differs but slightly from *officinalis* type, but in this I disagree. *P. o. Sabini*, received from the Oxford Botanic Gardens, and still in my charge, differs from *officinalis* type botanically more than any other form of *officinalis* that "D. K." mentions, and I will even go so far as to say that it is not merely a form of *officinalis*, but a hybrid—a hybrid which I prefer to class along with the forms of *officinalis* for horticultural purposes, but which, from the character of the growth and root structure, may have been a cross between *P. officinalis* type and a red form of the *albiflora* section. "D. K." says it blooms earlier, and that the shade of the flowers exactly corresponds with that of the double red. This, I admit as far as *P. officinalis* type and *P. o. fl.-pl.* are concerned, but *P. o. Sabini* flowers a few days later and has blooms of a lighter crimson shade, bolder and finely incurved petals, and is superior to *officinalis* in its normal character.

E. APPLETON.

St. John's, Worcester.

Clematis montana and Red Hawthorn.—Here a piece planted some years ago has nearly monopolised a large red Hawthorn, whose rosy

flowers appear along with and through the Clematis and make a lovely picture. The Clematis now covers a space of about 20 square yards, and is rapidly increasing.—GREENWOOD PIM.

Spiræa palmata alba.—This *Spiræa*, the counterpart, except in colour, of the well-known *S. palmata*, proves itself to be a worthy companion to the typical kind, and under glass flowers equally well. Here, in Surrey, the situation is too dry to admit of this *Spiræa* showing its charms to the best advantage when in the open ground, but in pots and just brought on in a cool greenhouse they are magnificent. As soon as the roots are in active operation copious supplies of water must be given, and at no time should they be allowed to suffer for want of moisture. This white-flowered variety is so beautiful when in flower, that in time, no doubt, it will be as extensively grown as the typical form.—T.

Saxifrages.—Amongst the Aizoon group none are at present equal to the charming *S. Macnabiana*, said to be a hybrid between *S. cotyledon* and *S. Hosti*, though on close and microscopical examination I fail to see any resemblance to the former. The typical *S. Hosti* resembles it both in leaf and flower characters, the only difference being in the number and intensity of the spots. When we consider the rapidity with which plants are improved now-a-days, it will not be hard to believe that *S. Macnabiana* is nothing but a very fine form of *S. Hosti*. Be this as it may, it does not in the least detract from the value of this plant. The large purple-spotted flowers are charming, and their profuseness, together with the ease with which it can be propagated by offsets, add greatly to its value. It does well in the ordinary border, with the simple precaution of a few stones round the collars of the rosettes. We have also found it flower well in pots, and in this way it will be a most useful addition in the greenhouse and conservatory, simply wintering the plants in cold airy frames during the winter and the spring. *S. cochlearis*, *S. lingulata*, and its varieties *lantoscana* and *superba* are very showy, as well as the rather rare *S. Kolenatiana*, with pinkish flowers.—K.

Early-flowering Gladioli.—Growers of these are so confining themselves to the pretty white form of *Gladiolus Colvillei* as to overlook the fact that there are others quite as worthy of cultivation, and presenting charming hues of colour. I saw early-flowering varieties in bloom at Reading a short time ago. The following were extremely pretty and very free, as three bulbs in a small pot had produced between them five and six spikes of bloom, and had they been in larger pots and afforded more root room, there is no doubt they would have flowered more freely. The best method of culture appears to be to put three bulbs in a pot in September. Keep them in a cold frame during autumn and winter, and then allow them to flower naturally. They can also be forced in the same way as the white variety. The collection includes *Fire King*, brilliant scarlet with pink and magenta flakes, showy and distinct; *Delicatissima*, white, delicately suffused with satiny pink; *Blushing Bride*, white ground, with crimson markings on the lower segments; *Rosy Gem*, clear bright rose, very free; and *The Bride*, the well-known pure white form. The first three being new varieties are not yet cheap in price, but once obtained they can soon be increased. One caution is necessary—fresh potted bulbs, if potting is not done until late in the year, should not be exposed to the action of sharp frost, or they are in danger of being destroyed. Perhaps the safest thing to do would be to plunge the pots in *Coccol fibre* if they are wintered in a cold frame.—R. D.

Wild gardening in Derbyshire.—I wish to note that the Belvoir Castle yellow Polyanthus is the most vigorous of its race, and can take care of itself almost anywhere. That American Wood Lilies can have too much shade (mine have no sun at all). It makes them lanky and drawn up. That *Hepaticas* thrive admirably on banks in a wood. *Cyclamen Coum* and *hederaefolium* will stand much shade if the drainage is good. That London Pride will

drive almost any weed before it in a wood. The same is almost true of the native Pulmonaria. Fine varieties of the common Columbine, good in wood, but far finer in kitchen garden. Campanula glomerata holds its own in a wood, with not much shade. Peonies, properly planted, master the coarsest woods. Lupines and Oriental Poppies thrive vigorously, or, rather, the former do, among weeds; therefore, if the weeds are removed, and wood Forget-me-not planted as a carpet, the effect should be good. Sidalceas, especially candida, thrive well in woods; weeds have no chance with them. Spiraea Aruncus in damp spots in woods very graceful, though scarcely as bulky as in borders. Monarda didyma does well in woods; Heuchera sanguinea I have not tried in the wild garden, but believe it will thrive anywhere. I have not yet found a position where it will not grow. Czar Violets grow in the woods more satisfactorily than in the borders, where frequent division is required. They have to fight with coarse Grass here. I have not room for more. But the destruction of Crowfoot and another weed that smells abominably requires great patience and assiduity in places where they are indigenous. — G. H. C.

The sun and the Poppies.—Certainly the flowers that love a grilling are having a "good time." But the high temperature and burning sun (rarely veiled by cloud) of the last week or more has shown how few flowers can bear it without showing some signs of distress. The Oriental Poppies seem least of all able to withstand it. The flowers that open in the morning are burnt white for half the depth of the petal by midday, and the next day nothing is to be seen but a little blackened rag. The variety bracteatum stands better, perhaps from the greater thickness of the petal. The early-flowering Clematises are much burnt; Tea Roses are bleached after their first hour or two—Fortune's Yellow turned to a washy pale buff, and all flowers go off as if in a hurry to get out of a world much hotter than they expected. — G. J.

SHORT NOTES.—FLOWER.

Antirrhinum asurgens—A good plant for dry walls. I notice that the bees are very fond of it.—W. B. H.

The Columbines are now in great beauty, and standards of yellow Austrian Brier crowded with blooms resembling those of Vase d'Or Potentilla.—W. B. HARTLAND, Cork.

Tufted Pansy, from Mr. Christison, Homewood, (this is the best, is of a pleasing colour, fine white, with purple-striped centre. It might be called Homewood if a better name cannot be found for it.

Double Pyret'rum Mont Blanc. This is one of the best of the double varieties, the flowers of rose shade, perfectly double, and pure white. It is largely grown for cutting.—E.

Alpine Pink (Dianthus alpinus).—This now brightens the rockery at Kew with its beautiful rosy pink flowers. When planted between Moss-covered stones, the effect is very pleasing.—E.

Armeria Lauchiana.—We noticed a tuft of this rare Thrift on the rockery at Kew. It is of the same character as our common Thrift, but the flowers are of a very bright rosy pink, and produced in a smallish head on stems from 4 inches to 6 inches high.—T. W.

Bletia hyacinthina.—This is flowering now, and when provided with a sheltered nook where the soil is of a moist, peaty character, it will live during ordinary winters. It makes a pleasing subject for the greenhouse; the flowers purple and produced with moderate freedom.—T. W.

Mont Blanc Pyrethrum.—A line of this over 300 feet in length is very beautifully backed with tall Delphiniums, oriental Poppies, white Rockets, and dark Peonies, &c.; grand to cut from. Is there a better form of double white? —W. B. HARTLAND, Cork.

White Fraxinella.—One of the noblest of border flowers; of long endurance, both cut and growing, and of clean, vigorous, and yet compact habit. Though beautiful in a border, and mixing well with any plants, it is perhaps best in a quiet corner by itself, where its dignified beauty may be enjoyed without distraction.—G. J.

Codonopsis ovata.—A pretty and interesting relation of the Bellflowers, with neat habit, and numbers of modest-looking, grey-lilac flowers, curiously ornamented inside with strong orange colour and black, and purple veining. The plant has one drawback—a strong smell, that may be pleasing to fox-hunters, but that the rest of the world would probably agree in calling nasty.—G. J.

Rock Pinks.—Most useful for covering spaces of bare ground are sheets of these neat little Pinks, presumably hybrids of cæsius and superbus; in great variety, but all pretty and sweet-scented. Among them this year has appeared a good double, of a pink colour, approaching the

common white garden kind in general growth, but with the edges of the petals in rather large, distinct blunt notches, that give the flower a look of some importance.—G. J.

Tufted Pansies.—These are used with excellent effect in Mr. Samuel Barlow's gardens, at Stakehill, Manchester, where they are employed to form single lines to beds and borders of Rhododendrons and other hardy plants. In the cool moist soil of the Stakehill district they root deeply, grow strongly, and flower freely all the summer, and scarcely a single plant is lost. A few fine and distinct fancy varieties, some of the best of the English show varieties, and a few of the most distinct of the Violas are most effectively employed. Some of Mr. Barlow's large clumps of Rhododendrons are raised above the level of the Grass plot, and under the shade of the outside branches, Mr. Barlow plants choice seedlings of gold-faced Polyanthus. The situation being cool and shaded, the plants make free growth and bloom in the best form, when the most promising varieties are marked and lowered the following season in order to test their value against named varieties.—R. D.

Indian Primulas—In THE GARDEN, June 18 (p. 552), the letter of Mr. Douglas on the Himalayan Primroses is, to me, most interesting and instructive, interesting because I, too, sowed in January, 1886, about twenty packets of seeds from India, each labelled with the name of some Primula or Androsace, and with nearly the same result as Mr. Douglas. The instruction I get is that the yellow Primula japonica, of which the seed came amongst that labelled elongata, is really P. prolifera (Wallich) syn. imperialis. I have only one plant, and now I have compared the characters in Hooker's "Flora" I stand corrected. I much fear that I weeded out other seedlings supposing them to be P. japonica, of the seed of which my soil is full. P. geraniifolia I flowered and discarded; it is too like the shabby P. mollis, and both resemble inferior forms of P. cortusoides; at least, they will never make good outdoor plants, and are not worth house room. P. bellidifolia, which a friend has now sent me, did not come up amongst my two forms of P. capitata, both of which are distinct from three or four varieties of that species I had before; one has a small dark purple, half-closed corolla and narrow upright leaves, and flowers in spring; the other has broad pro-cumbent leaves and a large truss of paler open flowers, and flowers in autumn. P. glabra, P. pusilla, P. sapphirina, poor things at the best, died in winter. Two or three unknown species are now growing, and I hope will flower next year. I find one, P. reticulata (true to character), which had tried to flower, but the slugs had eaten off the corolla. I did not succeed in finding any P. Kingi. The seed produced only P. sikkimensis.—C. WOLLEY Dod, Edge Hill.

Hardy Azaleas in bloom.—These Azaleas under suitable conditions may be relied on to furnish a wealth of flowers which will not be surpassed, if equalled, at this season by any other class of shrubs. There is among them a great wealth of colour, the blooms varying from white to bright crimson. One character in particular that places them ahead of their gorgeous allies, the Rhododendrons, is the pleasing fragrance of their blossoms. It is by no means strong, yet when there are several specimens together, especially early in the morning, the scent is most agreeable. For some reason they are not planted so largely as one would suppose, for it is commonly believed that peat soil is absolutely necessary for their well-doing; but such is by no means the case, as they will grow very well in loam, especially if it be lightened by an admixture of leaf-mould. The principal consideration is that they are so situated that the soil is always moist, even during the heat of summer, for without this they will not thrive. There have been of late years some valuable acquisitions to this beautiful class of plants, yet for all this many of the old kinds are magnificent, such, for instance, as those that used to yield such a grand display at the once prominent Fulham Nursery, and those that are still the principal attraction at Kew during their flowering season. Besides their beauty as outdoor shrubs, these Azaleas are among the most useful of any for

forcing into bloom, as from their dense mass of roots they can be readily lifted without injury, and after flowering again planted out. The flowering season of these Azaleas is spread over a considerable period, commencing with A. rhombicum and a near ally, Rhodora canadensis, both with purplish flowers, that are among the first to expand of any hardy shrubs; then, after the bulk is over, comes A. occidentalis and the many late-flowering hybrids raised from this.—T.

Eremurus Korolkowi.—I forward you one of two spikes of the above. The flowers have faded almost as fast as they have opened in the bright sunshine we have had. They seem more curious than pretty. The stamens are very conspicuous and keep bright for days after the flowers fade. I believe it has been stated that this plant has not been known to flower in England. There should be no difficulty about its flowering from the appearance of the plant here, which is growing in ordinary garden soil, and gets no shelter except from some shrubs at the back of it.—JOHN C. TALLACK, Livermere.

* * We quite agree not a pretty species, so far as we can judge. Some of the kinds are particularly beautiful, such as Eremurus Bungei.—Ed.

Motions of plants.—If written by an intelligent observer, an essay relating to the diverse motions of plants under various conditions would be exceedingly interesting. One of the most noticeable is the tendency of foliage to contract or gather together at night. I have remarked that feature particularly both in Potato and Tomato plants, and whilst hard to find any special reason for the motion in this country, yet the plant may have had excellent reason for it in its native habitat. Just now, for instance, Potato plants, when the leafage is gathered up at night, look 6 inches taller than in the day, when the foliage is fully expanded. Flowers also show many varied peculiarities of motion, not the least noticeable of which is their tendency to follow the sun in its diurnal course; that, however, seems to be dependent upon the sun's power of attraction. The closing up at night of many flowers is not so explicable, and is due either to absence of light, or to a power to exclude humidity or moisture. I have elsewhere mentioned Chrysanthemum multicaule, the flowers of which entirely close up at night, and their stems even bend somewhat so that the flowers become almost pendulous. On the other hand, the flowers of Chrysanthemum coronarium Sunbeam, a hybrid from that species, crossed with segetum, all droop their petals at night so much that the broad disc seems to shelter them entirely. On the other hand, the flowers of C. segetum with me remain expanded at night.—A. D.

Orchids v. hardy plants.—The resolution recorded in THE GARDEN (p. 476) by Mr. G. F. Wilson, of Weybridge, "that as his hardy and half hardy plants now take up all his available time, therefore his collection of Orchids will be sold at Stevens's on June 2," is, to my mind, a very significant example of the tendency of the time in flower gardening. Mr. Wilson gives the preference to the less pretentious, but equally beautiful, and in many ways more interesting hardy plants. I have often thought how different our gardens and pleasure grounds might have looked by this time if only the money that has been spent on Orchids had been expended on hardy plants. Imagine what displays we might have had if only Daffodils, Lilies, Primroses, and the like had been planted in sufficient masses everywhere, and which have now to be done piecemeal. The most folk can do at present is to indulge in small patches of things for the price of the really good things and the cost of remodelling our gardens to suit have rendered greater efforts unpracticable. A good many proprietors are following Mr. Wilson's example as regards the abandonment of the Orchids at least.—J. S.

* * The expenditure on gardens now is enormous, and all "J. S." desires may be secured by turning it in a more healthy direction. The outdoor garden deserves by far the most attention, but it would be a mistake to suppose that Orchids are not of high importance. It is true that many country gentle-

men are giving up their collections, but many more are adding to them, as the sales in London testify. Orchids are increasing in favour every day, and beautiful hardy plants in a far greater degree. It is also well known that beautiful Orchids once sold at very high prices are now frequently sold for less than one shilling apiece. On the other hand, there has been such a run on hardy flowers, that weak, wretched specimens are often sold at half-a-crown. We believe that the wonderful change in the price of Orchids is destined to make them extremely popular. In a climate like ours in winter the growth of beautiful things in houses rightly charms many people, and the thing is only to be regretted when everything else is pushed on one side, as if the world was meant to be covered with glass sheds.—Ed.

PROPAGATING.

HARDY SHRUBS.—A great many of our hardy shrubs can now be struck from cuttings, provided there are suitable appliances at hand for the purpose. The cuttings are formed of the current season's shoots, and as they are naturally very delicate they will require to be placed in a frame, and carefully attended to in the matter of shading, watering, &c. The shrubs that can be struck in this way include among their number Weigelas, Lilacs, Philadelphus, Deutzias, Hydrangeas, *Andromeda japonica*, *Choisya ternata*, *Hypericum*, and a host of others. A good time to take the cuttings is just as the young shoots lose somewhat their succulent character, but before they become really woody. In taking the cuttings it should be borne in mind that, in common with most other subjects, the weaker shoots will strike in a more satisfactory manner than the very strong ones. Unless a large number of any one kind is required the better way is to put the cuttings in pots, as by these means, when any particular kind is rooted sufficiently, it can be removed to more airy quarters; whereas if simply dibbled in the ground and covered by a frame some will strike quicker than others and need exposure, while others will not be rooted. By putting them in pots this inconvenience is entirely prevented. About 4 inches is a good length for most cuttings, and generally it is better to cut them off clean at a joint, removing just sufficient leaves for the purpose of insertion. A very convenient sized pot for the purpose is one 5 inches in diameter, and it should be drained with broken crocks for about one-third of its height, the remaining space being filled with soil, leaving, however, just space enough for a thin layer of sand on the top. A very good compost for the cuttings is equal parts loam, peat or leaf-mould, and silver sand, the whole to be passed through a moderately fine sieve. The soil will need to be pressed down firmly, being finished off by placing sand on the top; it is better if lightly watered through a fine-rosed pot, as then it is much easier to dibble in the cuttings. In putting in the cuttings, overcrowding must be guarded against, and as the pots are filled a thorough watering must be given, when they can be placed in a frame prepared for their reception. In choosing a frame for the purpose care should be taken to see that the lights fit closely, and if so situated that it is slightly shaded from the full rays of the sun, so much the better. If the frame is at all exposed to the sun, it must be shaded by means of mats, and at the same time kept quite close. The lights may be taken off every morning for a little time, when the state of the soil can be ascertained, and any cuttings that require it may then be watered. At the same time this affords a good opportunity to remove any signs of decay that present themselves, for in such a close atmosphere it rapidly spreads, and will soon carry off great numbers of cuttings. In speaking of a shady spot for the frame it should be borne in mind that at the same time a light position must be chosen, and, if shaded by trees, where it will be quite clear of the drip from them. From a month to six weeks will suffice for most of the different subjects to root, and the best way then is to pot them in small pots, and if a frame is available, replace them there for a week or two till root action

recommences, when they may be plunged out of doors in as sheltered a position as possible, and the following spring planted out. With regard to the soil, it may be noted that for most Ericaceous plants sandy peat is preferable to the compost above mentioned. A great many shrubs will not be sufficiently advanced yet to furnish cuttings, but some will be, especially those growing in sheltered spots, so that attention must first be directed to such as these, for when once the shoots are in a suitable condition, they soon (should the weather be hot and dry) become too hard. Besides the subjects above mentioned, the different evergreen kinds of *Euonymus* all root well in this way, and so does that ever popular climber, *Veitch's Ampelopsis*. In the case of this last it will root in less than a month, but to succeed well the young plants should be wintered in a cold frame, as if they stand outdoors during the first winter the weaker growth is often killed back for some distance. Another shrub that does very well with me treated in this way is that grand variety of the *Pyracantha Thorn*, known as *Lelandi*, for, being in want of a quantity, I last year put in a number of cuttings, and had the satisfaction of seeing them nearly all rooted before winter. They were allowed to remain in the store pots till early in the spring, when they were potted off, and last month planted out. A great many of these hardy shrubs can be struck in the open border without any glass appliances whatever, but by summer striking the greater part of a season is gained, and, what is often of much importance is, that under glass the cuttings can be made a great deal smaller, and in the case of a new or slow-growing shrub this is a great consideration.

HARDY HEATHS.—The majority of these beautiful low-growing shrubs can be propagated to a limited extent by division, especially where a specimen has been planted rather deep; but the Tree Heath does not admit of increase in this way, so that it is necessary to strike them from cuttings, and that is the principal method available for the propagation of any of them where considerable numbers are required. The treatment needed is much the same as that for the greenhouse varieties—viz., select as cuttings the tops of young shoots, and after stripping off the bottom leaves dibble them into pots of sandy peat. A length of 1½ inches to 2 inches is very suitable for the cuttings, and the leaves should be stripped from nearly one-half of that length. The leaves must be cut off carefully, so as not to bruise or injure the bark in any way, and the cuttings dibbled in quickly. To allow this the pots must be prepared beforehand, by filling them to within a couple of inches from the top with crocks, then over this place fine sandy peat pressed down very firmly, with some pure sand on the top. The cuttings succeed best if covered with bell-glasses, but where there are none at hand a very close frame must be chosen for their reception. From the delicate nature of the young shoots, the better way is to cover them with a bell-glass, and after that place them in a frame, as by the double covering a more regular state of moisture is maintained. Seeds of many hardy Heaths are often available, and of course young plants can be raised in this way. From the minute character of the seeds, they should be sown in well-drained pans of sandy peat, the covering consisting of a slight sprinkling of silver sand. If a pane of glass is laid over the pan, the soil is always kept moist and the germination of the seeds therefore much assisted. When the young plants are large enough to handle they may be pricked off into other pans, using much the same soil as before. By sheltering them with a frame during their earlier stages, they make much more rapid progress than if placed out of doors so soon.

BRAMBLES.—The beautiful double-flowered Brambles form such conspicuous objects during the latter half of the summer, that a note as to their ready propagation may be of interest. They can be easily increased by pegging the points of the young growing shoots to the ground, when they will soon root and form a base from whence other shoots will be pushed up. This mode is available for all the rambling-growing kinds of Bramble, which, strange

to say, hardly ever root except at the points of the branches.

TECOMA RADICANS.—As an illustration of the readiness with which this climber can be propagated by root cuttings, I may mention that last autumn, having occasion to remove a specimen against a wall, some of the roots were broken during the operation, and already a number of young plants are making their appearance, some of which have their origin from a piece of root not more than an inch long and no thicker than a straw. Though well known that this *Tecoma* can be readily increased by root cuttings, treated as they usually are, I never before noticed such rough-and-ready treatment of the roots to yield such good results. T.

GARDEN FLORA.

PLATE 602.

AUTUMN OR WINTER DAFFODILS.

(WITH COLOURED PLATE OF *STERNBERGIA LUTEA* AND *S. ANGUSTIFOLJA*.)

The accompanying plate represents a class of bulbs to which far too little attention is given at the present time, and for this lack of interest the uncertain character of our late autumn and winter months has, no doubt, much to do. The yellow Crocuses help at present to carry us through the dull months, but the flowers of the *Sternbergias* are of much firmer texture, and thereby are able to withstand a far greater amount of bad weather than the Crocuses, and in consequence are better adapted for our climate.

One great source of failure with these bulbs, and with many others of a like nature, is the fact of their being frequently grown in such positions as to necessitate their being disturbed at the wrong time or before growth has fully developed. In one or two gardens we have seen these grown in flower borders and lifted early to make room for bedding plants, and the wonder was that they never flowered. What these *Sternbergias* want chiefly is, thorough ripening in summer, and a slight protection, such as dry litter, &c., during the winter. It will depend upon the nature of the soil, as well as the position in which they are grown, whether they will have to be lifted or not. If the soil is heavy and clayey, the best plan will be to lift them when the leaves have died down and let the bulbs ripen, in the same way as *Anemone fulgens*, &c. In light sandy soil and fully exposed to the sun's rays they will in all probability get the necessary ripening without being lifted, and in this case the only plan will be to leave them undisturbed until the bulbs attain flowering size.

The species, as described and arranged by Mr. Baker, are as follows:—

S. COLCHICIFLORA.—This is one of the old garden plants, having been cultivated long ago by Clusius and Parkinson—by the first as *Narcissus persicus*, and by the latter under the name of the lesser autumn or winter Daffodill (*Narcissus autumnalis minor*). Parkinson in his "Paradise," says "that Clusius setteth down that the manner of the flowering of the lesser Daffodill is more like unto the Persian Daffodill than unto the great autumn kind." This has since been confirmed by Mr. Baker, including them both under the above species. M. Bieberstein, who was well acquainted with the locality of this species, describes it as possessing the most delicious fragrance, and perfuming, with its Jessamine-scented flowers, the fields of the Crimea, especially about the Bosphorus. The leaves are narrow, linear, and produced along with the fruit in spring. The flowers appear in autumn at about the same time as those of *S. lutea*, perianth segments

* Drawn for THE GARDEN in Mr. Geo. Paul's nursery, at Broxbourne, November 20, 1886, by H. G. Moon, and printed by G. Severeys.

nearly 1½ inches long, and of a very pleasing pale or sulphur yellow. It is found on dry exposed positions on the Caucasian Mountains, Crimea, &c., and is perfectly hardy in this country, treated in the same way as *S. lutea*. *S. dalmatica* and *S. pulchella* are varieties.

S. CLUSIANA (Ker, not Boissier).—*Narcissus persicus* (Clusius), *Amaryllis citrina*, *A. colchiciflora*, *S. atnensis*, and *S. Schuberti* are synonyms.

S. FISCHERIANA is nearly allied, and has the habit of *S. lutea*, from which it differs chiefly in flowering in spring instead of autumn, and by its stalked ovary and capsule. It is a native of the Caucasus, perfectly hardy in this country, and is the *Sporanthus Fischerianus* of Herbert's "Amaryllidaceæ," 46.

S. LUTEA.—This is the great autumn or winter Daffodil (*Narcissus autumnalis major*) of Parkinson, and of which he says:—

The great autumn Daffodil riseth up with three or four fair broad and short leaves at first, but afterwards grows larger of a very deep or dark green colour, in the middle of which riseth up a short, stiff round footstalk, bearing one fair yellow flower on the head thereof (inclosed at the first in a thin skin or husk), and consisteth of six leaves, as the former with certain chives in the middle as all or most other Daffodils have, which passeth away without show of any seed or head for seed; although under the head there is a little green knot which peradventure would bear seed if our sharp winter did not hinder it. The root is great and round and covered over with a blackish skin or coat.

The absence of seed on this bulb in a cultivated state is rather remarkable, seeing how plentiful it is and also how profusely it flowers in many parts of the country. The only seed we have yet seen has been obtained from dried specimens collected in the neighbourhood of Palestine. The same ex-

Mount Etna Lily (*Sternbergia etnensis*).

perience has been recorded by Dean Herbert in his "Amaryllidaceæ," where he says:—

It is strange that no writer has described the seed of this plant, which is much cultivated, nor have I ever seen it. Hill speaks of sowing the seeds in beds as if he had readily obtained it, and asserts that the seedlings vary much in the shade of yellow, and he gives a figure of a double variety, which is probably lost. The only variation which I have seen is a narrow and a broad leaf, hardy, but the bulbs often rot with me in the open ground if the summer is wet; probably they should be taken up and dried when the leaf decays.

From the above it will be observed that Parkinson and Herbert agree with regard to these plants; difficulties of climate, &c., have had to be overcome then, as now, before success in any form could be attained. Our experience leads us to the conclusion that the bulbs must be large before they will yield flowers freely, and, as is usually the case with imported bulbs, they are generally small and will take a year or two to attain flowering size. *S. lutea*, well represented in the accompanying plate, has five or six leaves, about half an inch broad, about a foot long, and produced at the same time as the flowers in autumn and winter. It is the *Amaryllis lutea* of the *Botanical Magazine* (290), *Oporanthus luteus* of Herbert's "Amaryllidaceæ," and is supposed by some writers to be the Lily of Scripture, as it grows abundantly in the vales around Palestine, &c.

S. ANGUSTIFOLIA (see coloured drawing to the right of *S. lutea*) appears to be merely a narrow leaved form of the type; it is very free-flowering,

and grows rather more freely than *S. lutea*. *S. graeca*, from the mountains of Greece, has very narrow leaves and broad perianth segments. *S. sicula* is a form with narrower leaves and segments than the type, while the Cretan variety has considerably larger flowers. Native of the Mediterranean regions.

S. MACRANTHA.—This is a really handsome species, though comparatively rare in cultivation as yet. The leaves are blunt and slightly glaucous, about an inch broad when fully developed about midsummer, flowers bright yellow, produced in autumn, the tubes somewhat cylindrical, 2 inches long, segments oblong, 1 inch to 1½ inches broad, with stamens about half their length. A native of Palestine, Syria, Western Persia, Asia Minor, &c. It has also been known under the names of *S. latifolia*, *stipitata*, and *Clusiana* (Boissier, not Ker).

STOVE AND GREENHOUSE.

T. BAINES.

LILIUM UMBELLATUM.

THE Lily season commences with the flowering of the different forms of this Lily known either as *L. umbellatum*, *L. bulbiferum* or *L. davuricum*. They are all characterised by large heads of upright, mostly cup-shaped flowers, varying in colour from reddish orange to deep velvety crimson. This Lily is of very easy culture, and large numbers are imported into this country from Holland at a very cheap rate, and are readily sold either for pot culture or for planting in borders. It may be relied on to flower the first season after planting, which is by no means the case with all, a noticeable example of which is *L. monadelphum*, which I have never yet succeeded in flowering satisfactorily the first year it was planted. Some eighteen months ago I planted a clump of this Lily, and all I saw of it last season was a few leaves, that just pushed through the soil and then died down again. This year, however, all the bulbs here pushed up strong spikes, and have several flower-buds. *L. umbellatum* differs widely from this; for even if bulbs had not been potted or planted till the early months of the new year, they will be now in full bloom. They are better, however, if potted before Christmas, as then the roots have plenty of time to take a good hold of the soil; consequently, the stems are stouter, and the flowers better developed than if the potting was delayed later. If the soil is at all light, the bulbs should be planted 6 inches below the surface, but in stiff loam or in pots they need not be buried quite so deeply. A very good plan either in potting or planting is to surround the bulbs with sand, in order to carry off any accumulation of moisture around them. These Lilies do best when treated as Hyacinths or Tulips, viz., potted in good soil, placed on a drained spot, and covered with ashes till the tops push through the soil, when the covering must be removed. As the pots get full of roots an occasional watering with liquid manure will be of service. Sometimes aphides will attack the young buds when about half grown, but that seldom happens, though should it occur, the pests must be at once removed by dipping in tobacco water. T.

Cereus C. M. Hovey.—A great many Cacti merit more extended cultivation, from the beauty of their flowers as well as from their easy cultivation. None of them are more showy than *C. speciosissimus* and its varieties, of which *C. M. Hovey* is one. Of this I obtained a plant six years ago through seeing a coloured plate which at that time appeared in THE GARDEN, and since then it proved that the distinction was thoroughly merited. The blooms are much like those of *C. speciosissimus*, except in colour, which in this variety is a kind of vivid scarlet, flushed with violet-purple. No description could do justice to the peculiar satiny sheen that overspreads the flower, and the brilliancy of its colouring seems to be further enhanced by the cluster of stamens in the centre of the flower. Besides this, we have in bloom *Phyllocactus crenatus*, with large, sulphur-coloured blossoms, which, from their distinct tint, are very noticeable among their brighter-coloured asso-

ciates. Plants of these flowering Cacti, and more especially *C. speciosissimus*, may often be seen in cottage windows in rude health and bristling with flower-buds. Where glass structures exist, a shelf near the roof, or in some such spot where few plants would thrive, is just the place for this class of plants; and they do well in a mixture of good loam, broken brick rubble, and sand, with a little dry cow manure. When in full growth they must be fairly supplied with water, but afterwards they may be kept somewhat drier in order to thoroughly ripen the young growth. In winter they may be kept almost without water, giving them just enough to prevent shrivelling. Pieces of the branches, taken off at any season except in the depth of winter, potted in the soil above recommended (but less rough than for established plants), and stood on a shelf, will soon root.—H. P.

MIGNONETTE CULTURE.

THOSE who require fine plants of Mignonette for autumn and early winter flowering ought to make two sowings of seed, the first one about the middle of June, and the second about the middle of July. For several years I have adopted the following method, and have always found it answer satisfactorily: Take as many 6-inch pots as there are specimens required, and after draining them well fill to within an inch of the top with a mixture of loam and rotten manure well broken up; press it down rather firmly and sow the seed thinly, and cover lightly with finely sifted soil. Place them in a shady place, either in a frame or under hand-lights. After the seedlings are up give more air night and day. The plants will soon become strong enough for the first thinning to take place, which should consist of the weakest plants. In a short time a second thinning will be required, leaving from nine to eleven of the strongest plants at regular distances over the surface of the pot. These may be allowed to grow until they have rooted well, but at the same time they must not be allowed to get pot-bound, as if so, the stems become hard; they will attempt to bloom, and their future growth will be checked in consequence. At this stage they will be fit to put into the pots in which they are intended to flower. This large shift is necessary, because Mignonette does not thrive well when frequently shifted. I use 11-inch or 12-inch pots, inside measurement. They should be perfectly drained and quite clean. As to soil, I have tried several mixtures, but have found none to equal turfy loam twelve months cut and decayed, and which has been frequently soaked with farmyard liquid manure. This will, without any addition, grow the plants well. Pot them firmly and water at once, keep the sun from them, and stand the plants outdoors on a cool bottom of ashes and protected from strong winds. Stake each plant firmly at first, and when they have grown an inch or two take out the top of every shoot; this will cause them to break 2 inches or 3 inches down the stem. These shoots in due time will need stopping and tying as the plants advance, until they have formed the outline of good specimens, when they may be allowed to flower. At the latter part of the summer, when the plants are taken under cover, they should have a light airy place in a greenhouse temperature. A caterpillar very similar in colour to the foliage and at first very small will commit sad havoc if not watched and destroyed. When the plants are well set with bloom a top-dressing of rotten manure should be given to them, and when the surface roots find their way into this, weak liquid manure should be applied twice a week, which will assist the plants when flowering, and give a good return for the labour bestowed upon them.

Folkington Manor.

THOMAS RECORD.

Greenhouse Rhododendrons.—In the list of greenhouse Rhododendrons given in THE GARDEN (p. 514) there is an important omission, for no notice of these beautiful plants would be complete without the bright-coloured perpetual-flowering *R. Duchess of Edinburgh*, as it is one of the finest of all the tube-flowered section, and of more bushy habit,

besides being more free-flowering than R. Davis' which, last, however, is well worth a place, but not to the exclusion of the other. As far as my experience extends, R. Duchess of Edinburgh and R. Princess Alexandra (blush) are the most continuous blooming of all the many varieties.—H. P.

Hoya bella.—The best position for this is, when treated as a basket plant, in the stove, as then the slender, drooping stems reach for some distance, and just now it forms a most beautiful object, for the whole plant is thickly studded with clusters of blossoms that nestle among the neat, dark green foliage. The individual flowers are star-like, and of a waxy texture, and remain in beauty a long time. Like the other members of the genus, this *Hoya* needs a good, open soil, and but limited root-room. Several of the *Hoys* are very desirable flowering plants, the good old climbing *H. carnosa* standing in the front rank, but for hanging baskets *H. bella* is the most useful.—H. P.

Sollya linearis.—Flowers of such an intense blue as this are by no means common among greenhouse plants, and on this account alone it deserves a passing notice. It is a medium growing climbing plant with slender wiry stems, narrow deep green leaves, and small drooping bell-shaped flowers of a beautiful clear blue colour. This plant, in common with the other natives of New Holland, needs the protection of a greenhouse, and there it may be employed for furnishing the smaller rafters as a screen plant, or trained around a few sticks and allowed to flower as pot specimens. By this last method nice little plants may be obtained in pots 5 inches or 6 inches in diameter, and when not larger than this, they will flower profusely, especially if struck from cuttings, for plants raised in this way flower in a young state more readily than seedlings.—T.

Pyramidal Rockfoil (*Saxifraga Cotyledon*). When well grown, this will push up a flower-spike 18 in. to 2 ft. high, and form a pyramid of pretty white blossoms. It is only within the last few years that it has been extensively cultivated, yet it has now become one of the standard plants among the London market growers. It is a plant of easy culture, but in order to obtain the best results the plants should be wintered in a frame free from drip, and when the flower-stems commence to push up be removed to a greenhouse. Loam, with a little sand and leaf-mould, will suit it well, and good specimens may be obtained in pots 5 inches in diameter. The plant, especially after flowering, produces in quantity offsets, by which it can be readily increased. Water during the winter months must be sparingly applied, and at the same time care must be taken that it does not lodge in the centre of the crown, as, if so, the future flower will be destroyed.—T.

SHORT NOTES.—STOVE AND GREENHOUSE.

Habrothamnus elegans.—This elegant climber is flowering profusely in the conservatory at Gunnersbury House. The specimen is in the most vigorous health, and, associated with clusters of the same graceful character, presents a pleasing picture.—C.

Fuchsia Monarch.—This *Fuchsia* is in bloom now in the greenhouse at Kew. Though an uncommon variety, it is well adapted for pillars and rafters in comparatively small houses, and *Fuchsias* might be more often used in this way than is at present the case. The flowers of this variety are large and well coloured.—E.

Canna iridiflora Ehemanni.—This is a most useful plant for the conservatory or greenhouse, its leafage being handsome and the flowers of a rich crimson. Those who have not yet grown it in pots should do so, as not only are the plants of noble appearance, but the individual flowers can be used with advantage in bouquets and epergnes.—E.

Diseased Marguerites.—I enclose you a few leaves of the above affected with some disease. It is since the plants have been put out that it has shown itself. Is there any cure for it, or would it be best to destroy the plants?—W. H.

Your plants are affected with the Marguerite Daisy fly (*Phytomyza affinis*), and the only way to get rid of the pest is to destroy the plants when they are badly infested.—Ed.

Ivy-leaved Pelargonium Madame Crousse. Although an old variety, still remains one of the best. We saw a fine batch at the Bush Hill Park Nursery of Messrs. Low. The plant grows freely, and produces a profusion of large trusses of rosy pink flowers, the colour bright and

telling. These double Ivy-leaved varieties will be found very useful for hanging baskets, and also do well when used for the decoration of window boxes.—G.

Terminalia elegans.—As Mr. Baines has drawn attention to this plant, cultivated under this name, I wish to know whether it has been flowered by him or anyone else. It is not a *Terminalia*, nor does it belong to the Order Combretaceae. It is, I believe, an *Aralia*, and this is shown by the fact that it may be grafted on plants of that genus. I have not yet been able to flower it, and I should be greatly obliged for a flowering specimen.—R. IRWIN LYON, *Botanic Gardens, Cambridge.*

Scarlet-flowered Skull-cap (*Scutellaria Mocciniana*).—We saw this recently making a brilliant display in the greenhouse at Kew. The flowers are rich scarlet and the leaves handsome. When the plants are judiciously used, they produce an agreeable effect; but flowers of quieter colouring should be intermixed with them, so as to tone down the vivid scarlet. It needs stove treatment, but plants, when in bloom, may be brought to the greenhouse without harm.—T.

ADENANDRA.

A GENUS of the Rue-wort family, nearly allied to *Diosma* and *Barosma*; the leaves of all these genera have a peculiar Rue-like smell, due to the strong volatile oil which they contain, and are used largely by the Hottentots to perfume their bodies; they are also used medicinally under the name of "Bauck." *Adenandras* are compact-growing shrubs, producing in profusion their handsome flowers. Pot in good fibrous peat and light loam in the proportion of three parts of the former to one of the latter, making the whole very sandy; drain well, and ventilate freely the structure in which they are growing. All are natives of South Africa.

A. FRAGRANS.—A much-branched, twiggy shrub, attaining a height of 1 foot to 3 feet, easily grown into a handsome specimen. Flowers terminal, but the young shoot usually starts into growth with the buds, and extends beyond them when open, which adds materially to the effect. Flowers showy, deep rose colour, and very fragrant. It blooms during May, June, and July.

A. SPECIOSA.—This species is also known as *A. umbellata*, *Diosma speciosa*, and *D. umbellata*. It is not so robust in habit as the previously described plant, and seldom exceeds 18 inches to 24 inches in height; stems reddish brown; leaves scattered (but closer together than is the case with *A. fragrans*), and fragrant when bruised. Flowers arranged in terminal umbels (destitute of the protruding young shoot) usually six to eight together; the buds reddish crimson, changing in the expanded flower to a delicate pink, the centre of each petal being streaked with red. It blooms during May and June.

A. UNIFLORA is a most desirable plant for greenhouse decoration. It is undoubtedly nearly allied to the preceding; the leaves of *A. uniflora* are similar to those of *A. speciosa*, but are smaller. Flowers solitary, nearly terminal, white, the reverse side pink. It blooms from April to July.

Rhodanthe Manglesi.—At one time this was considered to be a very difficult plant to cultivate in a satisfactory manner; but of late years it has been taken up by some of the growers for Covent Garden Market, the result being those beautiful little specimens that are such common features in London at the present time. The principal points to bear in mind in the cultivation of this *Rhodanthe* are, first, that plenty of fresh air is essential to its well-doing; and, secondly, it is very impatient of being disturbed at the roots. The specimens usually met with are in 5-inch pots, and generally the seeds are sown in the same pot as that in which they flower. This does away with the necessity of disturbing the roots, and as a further preventive, care must be taken, if they are on a stage in which there is any material they can root into, to see that this does not take place, otherwise when moved the plants will be greatly checked. In sowing it should be borne in mind that the young plants are to remain in the same pots, and consequently more space must be left for water than if the seedlings were to be potted off. The seed may be sown in the greenhouse about the end of February, and when the young plants are above ground plenty of air must be given—indeed, they may then be placed in a frame, but it must be one in which there is a gentle heat

for a time. If kept too close, or the atmosphere is too moist, mildew is very liable to attack the foliage, the best preventive for this being plenty of fresh air. As the plants progress, and consequently the pots become full of roots, weak liquid manure twice a week will be of great advantage. In addition to this mode of culture, the *Rhodanthe* may be sown at this time of the year in the open ground, and under favourable conditions it will flower beautifully towards the end of the summer.—H. P., in *Field*.

WORK IN PLANT HOUSES.

ACALYPHAS.—These variegated plants can be effectively used in several ways, especially *A. tricolor*; this looks well both associated with large-leaved plants, such as *Alocasias*, *Caladiums*, *Anthuriums*, *Cyanophyllums*, and also with flowering subjects. The *Acalyphas* are of free growth, and when kept in a warm stove attain a fair size in little time. It is not advisable to grow large specimens, as half a dozen of moderate size look much better than one single example. It is when the plants are in 4-inch or 5-inch pots that they are most useful; in some places they are largely employed for table decoration and for placing about in rooms, halls, &c., during the summer months. The little time required for striking cuttings and growing the plants large enough for the purpose last named renders these *Acalyphas* equally as useful as *Coleus*. To keep up a stock for use in this way the cuttings should be struck at different times. If some are put in now made of the points of the shoots, consisting of three or four joints with two or three leaves, they will root quickly, and be ready for use later on.

CALADIUM ARGYRITES.—This when in a small state is the best of all the *Caladiums* for rooms. Most of the large-leaved varieties are too vigorous, and they are not so well able to bear a lower temperature than that of the house in which they are grown. Suckers of *C. argyrites* that were taken off in spring and have since become established should be put in 4-inch or 5-inch pots. *Caladiums* will succeed in either peat or loam with sufficient sand to keep the compost porous, but when the plants are to be used for decoration or the leaves are required for cutting it is better to pot them in loam, as then the foliage acquires a little more strength and substance. When tender plants are required to be used in places where the temperature is considerably lower and the atmosphere drier than that of the house where they are grown, it is necessary to treat them in a way that will impart the most strength and solidity to them. It is essential that the plants be kept near the glass, and have as much light and air as possible consistent with their growth. When they are stood close to the glass they require more shade in bright sunny weather. Where cut flowers are much in demand a good stock of this *Caladium* should be grown; when treated as here recommended the leaves will keep fresh for a week or ten days, and there are few things that have a prettier effect when arranged with flowers of suitable colours. When required for cutting care must be taken not to remove too many of the leaves from the plants; one-half may be cut without the bulbs feeling much of the effect, but if more are taken it will do harm. When any of the larger-leaved sorts of these plants are used in summer in conservatories, sorts that have the most green colour in the leaves, such, for instance, as the old variety, *C. Wightii*, should be chosen, managing them in the way advised for *C. argyrites*.

CUPANIA FILICIFOLIA.—In this we have one of the most beautiful of all the hard-wooded plants that are grown for the beauty of their leaves, yet it is rarely met with. Now and then a large specimen may be seen staged in a competing group of fine foliage plants, but small or medium sized examples for the decoration of warm plant houses and for temporary use in living rooms are rarely met with. Its elegant Fern-like foliage is seen to the best advantage when the plants are confined to single stems, in which form this and other things of a like character should always be grown. When the plants get bare of leaves at the bottom they should be headed down; the best time for this is

early in spring before growth commences, as then there is time for the production of a crop of young shoots that can be struck and grown into nice little examples before autumn. Plants that were headed down will by now have pushed several shoots, which may be all taken off and struck, retaining the stools to admit of their producing a second lot, or, if some large specimens are wanted, a single shoot may be retained to each, which, if the roots are in good condition, will soon make handsome heads. The cuttings should be put singly in small pots half filled with sand and sifted loam, the rest all sand. Treated in the usual way, with heat, shade, and moisture, in a confined atmosphere they will form roots. When the cuttings have rooted sufficiently put them in 6-inch or 7-inch pots; these will not be too large, as this *Cupania* grows very freely. Place them where they will get ordinary stove heat, with plenty of light to give strength and substance to the growth, as if the leaves are wanting in this they will be proportionately shorter-lived. Shade from the sun, and syringe freely every afternoon until the autumn, when it may be discontinued, giving more air and keeping the atmosphere somewhat drier. After sufficient cuttings have been obtained the old stools may be discarded or partially shaken out, repotted in new material, and grown on. Loam with some sand added is the best for the plant, as it gives more solidity to the leaves.

SMALL CROTONS.—Amongst the different kinds of plants with variegated leaves that are adapted for house decoration there are few, if any, so effective as the Crotons, especially the varieties with narrow leaves that droop more or less, such as *C. Weismanni*, *C. Warreni*, *C. majesticus*, and the old *C. angustifolius*; the last-named is the best for the purpose, provided the yellow colour is well brought out. Those who have had much to do with the cultivation of Crotons cannot but have observed that there is generally much difference in the colour of the leaves on the different shoots on the same plant; in selecting shoots for cuttings, none but those that have well marked leaves should be chosen, as plants raised from cuttings that have too much green in the leaves generally continue to be deficient in colour. Now when the spring growth has been made, so as to show the colour of the foliage, is a good time for striking a stock; the cuttings will root in two or three weeks if kept in a brisk heat, close, moist, and shaded. They are best struck singly in small pots, as then there is no disturbance of the roots when the time comes for giving a shift. Little, or no shade is required by Crotons further than may be found necessary to prevent the leaves getting scorched, as the more they are exposed to light and sun the more colour the foliage will usually get. They are not particular as to soil; they will thrive in either peat or loam, but in loam the plants generally have the most colour. Being warm stove subjects it follows that it is only in the summer and autumn that they will keep in presentable condition in a living room. Plants struck now and kept moving until the end of the growing season will be in right condition for use next summer, and when to be employed in this way they should be confined to a single stem.

PANDANUS.—Several of the Pandanus, both the green and the variegated sorts, do very well in rooms during the warmer part of the year, keeping in good condition a much longer time than most things that require heat. The green-leaved species suitable for use in this way are *P. elegantissimus* and *P. graminifolius*. The variegated sorts are *P. Veitchi* and *P. javanicus variegatus*. With the two last named, as in the case of the Crotons, it is important that the suckers chosen should have their leaves well coloured, as the green ones often produced seldom show much disposition to become variegated. Suckers in suitable condition for striking may usually be had at this time. In severing them from the old plants, care must be taken not to bruise the base; strip off a few of the bottom leaves, and put them singly in pots large enough to hold them. A mixture of loam and sand in equal parts will be best to strike them in, and

bottom-heat, if available, will assist them to root. Shade slightly from the sun. As soon as they are well rooted, stand them as near the glass as possible. A good deal depends on this in the ability of the leaves to bear the treatment to which the plants will ultimately be subjected. When they require a shift no larger pots should be used than are necessary, as in all cases when to be employed in the manner under notice, the smaller the pots the better the plants look.

CYPERUS.—Before growth commences is a good time to propagate these plants, but if there is any deficiency of stock the work may be successfully carried out now. Stock propagated now should be large enough to use next summer. In dividing established plants it is not well to reduce the pieces too small, as if this is done, it takes a long time to grow them to a useful size. Care should also be taken not to mutilate the roots more than necessary. Loam is preferable to peat for these plants especially the variegated sorts, as they generally come better coloured in it than in peat. Give pots large enough to hold the roots without unduly compressing them. Kept warm and a little close, with shade, they will soon get established; afterwards give abundance of light so as to keep the foliage stout and to give colour to the variegated varieties. The green forms of *C. alternifolius* and *C. latus* are both useful plants, but the variegated varieties of each are most prized. *P. latus variegatus* is a desirable sort, not so well known as it deserves to be.

T. B.

WATERING.

WHEN in a large market plant-growing establishment recently, I observed men engaged watering the plants in the houses and frames with the greatest impartiality by means of small hose attached to the water company's mains. It is a rough-and-ready method of doing work, which the great heat then prevailing rendered absolutely needful, but which still treated all plants alike, or possibly, in the effort to do so, left some indifferently moistened. However, there was this to be said in regard to the plants, all seemed to thrive under this mode of watering. The market grower, who has perhaps 100,000 or 200,000 plants to water, can hardly be very particular. The work must be done quickly, and there is little time for discernment. But then in many cases market plants are of a quick-growing, rapidly-absorbing kind, and are not too nice about their root dosings. They may find all the best elements of growth in light, airy houses, good soil, and small pots, and are indifferent to coddling; whilst private gardeners will make a fuss and bother about a few score of plants, and in the end, with all their fuss and bother, half-kill their plants; in fact, half-killing them with excess of kindness. The inference seems to be that kindness ill-placed is more destructive to plants than is rough-and-ready cultivation. It is certain that in no private places are plants produced so well, and so well, too, under such apparently disadvantageous conditions, as they are in market plant nurseries, and that seems evidence in favour of a free hand in watering. But whilst we are discussing methods of recouping to plants the root-moisture lost, the heat prevailing is rendering the labour of watering onerous and almost incessant. Really there is no work in plant houses during hot, dry weather which is so wearying, monotonous, and apparently profitless, as constant watering; whereas, in the large place I referred to, watering can be done direct from the mains; the labour is trifling if the time occupied is still excessive. But in most gardens all the water has to be brought from considerable distances, and the filling of small cans constantly promotes great waste and dirt. The work is hardly accomplished throughout before it is found needful to start again, and the constant repetition seems to lead to the inference that the labour is profitless after all. Of course it is not, for moisture is absolutely needful to the life and growth of the plants, but we know too well that far more of the water so freely given is not absorbed by the plants, but is lost by speedy evaporation; hence we water largely to give the

plants something to do as well as to keep the plants alive. Water in a state of purity furnishes little that is nutritive, but it serves to liberate solid compounds, and enables the roots to feed upon them. Still, repeated waterings, which are found speedily to evaporate or drain away, must rapidly diminish the nutritive properties of the soil in the pots, and it is most probable that far more exhaustion takes place in that way than through plant absorption. Then, constant waterings naturally promote the formation of small channels in the soil, through which the water passes rapidly, leaving much of the ball of earth untouched and too free air space after the water has passed away. No doubt the best summary of watering, as we have to practise it at this time of the year, is found in the expression that it is a necessary evil. The liberal employment of manure water enables us to recoup plants to some extent that loss of nutritive matter in the soil which such a long spell of pure waterings previously has produced, and there can be no doubt but that such waterings are wondrously beneficial. Liquid manures include considerable solids in a state of semi-solution, and these doubtless gradually block up the water passages and charge the exhausted soil with nutritive matter; hence we see plants even in small pots thriving wonderfully upon a course of liquid manure. These liquid mixtures, though usually called stimulants, are really foods, though given in a weak form, but are easily absorbed, and therein lies one of the chief values of liquid manures to plants, which, whilst making rapid growth, are yet root-bound in a very limited area. The need for constant waterings of plants in hot weather is greatly aggravated when the pots have narrow tops, or are somewhat tubular shaped. It is a fact, which I have proved after long experience, that whilst a pot may be too broad or spreading to be economical, it may also be too narrow or superficially restricted. Deep, upright pots are so far useful for small plants that they enable large numbers to be stood in smaller space; but, on the other hand, the gain in that direction does not compensate for the lack of power to retain sufficient moisture on the top, when watering takes place, to fully saturate the soil beneath when once it is dry. Ordinary shaped pots seem so far constructed that they enable the needful amount of water to be held on the surface of the soil to thoroughly saturate the whole of the root-ball. On the other hand, pans, for instance, need great care, as flooding them with water too often saturates the soil in them to a condition of sourness; indeed, almost of mud. After all, and in spite of the market-growers' rough methods, there is some intelligence and discrimination needed in watering. One difficulty is, however, that the work has to be done with a rush, under pressure of time, and with the best of will there is unfortunately little time for efforts to discriminate between the wants of one plant and those of another. An intelligent mechanic, who is also an amateur gardener, recently sent me some pots fashioned with double rims, the outer one being about 1 inch, or a little more, in depth, and having an interval of perhaps the fourth of an inch between it and the proper sides of the pots, which was intended to form a water reservoir, the belief entertained being that evaporation would in that way largely be arrested. Of course, such pots are cumbersome and heavy, and I found, after patient trial, that the result did not justify the designer's anticipations. The plants did not absorb the water through the porous sides of the pots, and the outer casing was not deep enough to save the whole of the pots from external heat, whilst the root absorption was as great as ever. A. D.

Nurserymen's practices.—There is, I am sorry to say, good cause for the complaints that have recently been made on this subject. Not long since I sent for some Anemone seed of a particular strain. In due course I received a packet of another sort, with the assurance that I should "be sure to like it." For a Daffodil that I ordered in the autumn, I got another kind of which I had plenty. I do not know of anything more

disappointing than, having written for one particular plant, to get another in its place. Another bad practice is that of sending a greater number to compensate for want of size. The "seven for six" often means that the plants are so small and weakly that they can never thrive as they should do.—
J. C. B.

FERNS.

W. H. GOWER.

GLEICHENIA (MERTENSIA GROUP).

THIS group of plants is exceedingly beautiful, and presents quite a different aspect to the true *Gleichenias*. They have long, wiry, creeping rhizomes, which render them difficult subjects to import in a living state, so that, although numerous species abound in tropical countries, few at present are to be found in our ferneries. Amongst the most beautiful kinds is *G. dichotoma*, which is widely distributed over the tropical and sub-tropical regions of both hemispheres, and naturally varies considerably in appearance from such widely separated localities. Many of these, when brought into cultivation, will doubtless prove distinct plants, although in a dried state their distinguishing characters are not readily discernible. The form of *G. dichotoma* to be found in cultivation is that received from Jamaica; the fronds are many times dichotomously divided, the pinnae being pinnatifid and the ultimate segments upwards of an inch in length, with a plain surface; the margins not revolute, as in the other group of the genus; bright lively green on the upper side, glaucous beneath.

G. PUBESCENS.—This plant, although abundant in Tropical America, is exceedingly rare in cultivation, and one that has hitherto proved somewhat difficult to manage; the pinnae are large, coriaceous in texture, the undersides and the midrib on both sides being clothed with a reddish brown tomentum, which is so dense that when the young segments are unfolding they have the appearance of being crested at the points. The upper surface of the pinnules is deep green.

G. FURCATA is a similar plant to the preceding, but differs in being destitute of the ferruginous tomentum so conspicuous in *pubescens*, but the underside of the segments is sparingly clothed with short, ashy grey hairs. All the above kinds require the temperature of a stove.

G. CUNNINGHAMI.—This species is peculiar to New Zealand; it is erect in growth, branched, and bears one or two whorls of flabellate fronds, the stems and midribs more or less clothed with reddish brown scales; the segments are deep green above, glaucous beneath.

G. FLABELLATA is perhaps the best known kind belonging to this group of the *Gleichenias*; it is widely distributed in Australia, and is also found in Tasmania, New Zealand, and New Caledonia. The stems rise erect to the height of 6 feet or more, bearing several tiers of large, smooth, fan-shaped fronds, which are bright green above, slightly paler beneath. When grown into a large specimen this species assumes the appearance and proportions of an elegant upright shrub. *G. flabellata* and *Cunninghami* are usually described as greenhouse Ferns, but they thrive best in the temperature of an intermediate house. Other forms belonging to this group, which are said by some to be varieties only, and which will be found well deserving of introduction, are *G. Bancrofti*, *gigantea*, *cryptocarpa*, *glauca*, *bifurcata*, *Klotzschii*, *Morrisii*, &c. The treatment these plants require and the soil necessary for their culture is the same as that recommended for the true *Gleichenias* in THE

GARDEN (p. 516), saying that the majority of them require a higher temperature.

OUR NATIVE FERNS.

THE SPLEENWORTS.

THE *Aspleniums*, or, as they are popularly called, the Spleenworts, form a most interesting genus among the British Ferns, and are particularly useful on account of the evergreen character which they all possess. The coriaceous texture of the foliage which distinguishes most of the ten species which are found wild in the various parts of the British Isles also greatly adds to their value as decorative plants, while the ease with which the strongest-growing kinds may be cultivated also tends to make these species particularly popular. Some of the very dwarf-growing sorts are somewhat difficult to preserve, especially in smoky localities; but these, besides succeeding fairly well in Fern cases, are rendered specially attractive through their constitution and mode of growth, and they may safely be termed the gems of our native Ferns.

shine, and when growing thus is very dwarf. It is also very useful for pot culture, as it thrives under glass in the cool house, even better than in the out-of-doors rockery. The soil in which it grows most luxuriantly is a mixture of leaf-mould, sandy loam, lime rubbish, and fibrous peat in about equal parts. Its propagation may be effected by means of seedlings, the spores being ripe about September, or by the division of the crowns in early spring, during March and April. This useful species has produced several variations, of which the most distinct are: *Asplenium A.-n. acutum* (see cut), with tripinnate fronds, about 12 inches long, and showing pinnules very narrow and divided into acute linear-lanceolate lobes decompositum, which occurs in Devonshire, differs from *acutum* in having the segments of the pinnules less pointed, also less rigid, and in being nearly quadripinnate. *A. A.-n. grandiceps* is a variety as handsome as it is remarkable on account of its fronds, which average about 9 inches in height, being terminated by a finely divided crest, while the smaller tassels at the ends of the pinnae render

The Lance-leaved Spleenwort (*Asplenium Adiantum-nigrum acutum*).

THE BLACK MAIDEN-HAIR SPLEENWORT (*Asplenium Adiantum-nigrum*), which is one of the common Ferns found all over the British Islands, has, on account of the lasting qualities of its foliage, within these last few years taken a prominent position, which it most likely will retain for a long time to come, as its dark shining fronds, when cut and mixed with flowers, retain their freshness for an almost unlimited time. As shown by our illustration, these are of an elegant shape, and are also produced in great abundance. Fronds of this have been lately very extensively sold under the name of French Fern, which name has no doubt been erroneously given to it on account of the enormous quantities brought weekly to market from the western part of France, principally from Brittany, where it grows abundantly. It is also found in Cornwall, Devonshire, Somerset, Hampshire, and in some other counties in shady places at the foot of trees and shrubs, as also in the hedges, in fields, on old walls, and in disused quarries. These are the positions in which the fronds of the Black Maiden-hair Spleenwort attain their greatest length, but it will also bear continued exposure to sun-

it very effective. In the variety *oblongum*, found in the Channel Islands, the fronds are oblong in shape, while those of *fissum*, originally found in Devonshire, are irregularly lacinate. The Argyleshire variety *oxyphyllum* is a small-growing kind, with very spiny-looking, toothed, and oval lance-shaped fronds. Finally, we have in *Asplenium A.-n. variegatum* a very rare sport, whose fronds are irregularly streaked and blotched with white, which variegation must not be confounded with the discolouration produced by the ravages of a green insect much resembling a small grasshopper, which frequently attacks hardy Ferns even in their wild state.

The Alternate-leaved Spleenwort (*Asplenium germanicum*) is in many ways the exact counterpart of the species above described, for it is a somewhat difficult plant to manage, specially in localities where the atmosphere is not pure and the air not bracing. It also produces its curious fronds sparingly, and these, as may be seen by our illustration, are hardly adapted for use in decorations. This variety is indispensable in a collection of hardy Ferns. As regards its native habitat, the

Alternate-leaved Spleenwort is also vastly different from the Black Maiden-hair Spleenwort, as it is exceedingly local, and has been found in England at Borrowdale and Scawfell, in Cumberland, on the Hylce Crags, in Northumberland, in Wales, near Llanrwst, and in the Pass of Llanberis. In Scotland, where it appears to be somewhat more abundant, though in no wise plentiful, it has been found on rocks in the Tweed, near Kelso, in Roxburghshire; near Dunfermline, in Fifeshire, and on the Stenton Rocks, near Dunkeld, in Perthshire. The name of germanicum, which was originally applied to this singular plant, and which it has retained to this day, does not in any way denote its origin, as it is found only very sparingly in Germany as it is also in Switzerland, and in some parts of France and Sweden. Its first discovery in this country dates from about 1792, when Mr. Dickson found it on some rocks in the south of Scotland, and published his discovery in the second volume of the Linnean

no relationship whatever. Its fronds, which are proliferous and of a dark green colour, are linear, and measure from 6 inches to 8 inches in length; their pinnae, short and oblong-obtuse, are refracted or thrown back, and have a peculiar and pleasing appearance. It is remarkable that although most of the exotic *Aspleniums* are proliferous, this is the only one of the British kinds possessing this character, and its inclusion among British species, though admitted by the late Mr. Thos. Moore, rests on very slight grounds. It is best cultivated under glass protection.

As a glance at our illustration will show, the Smooth Rock Spleenwort (*Asplenium fontanum*), whose lovely fronds seldom exceed 6 inches in length, is one of the gems among our native Ferns. But whence the specific name of *fontanum* is derived from it is difficult to say, as this pretty plant is found exclusively growing on old walls and dry rocks. Its habitats are of such a very local character, that its being a British Fern has frequently been questioned, but its rarity is easily accounted for and understood when we remember that, except in sheltered and thoroughly suitable situations, it is unable to withstand our climate. The question

situations. It is only in the second edition of Ray's "Synopsis Stirpium Britannicum," which was published in 1696, that we find this interesting plant given as a native of the British Isles, for it is stated there that Dr. Sherard had found it "on the rocks on the north side of the isle of Jersey." Some thirty years later, in the third edition of the same work, its discovery in England was first noticed, "Mr. Bobart having found it in the north porch of the church at Adderbury, in Oxfordshire. Dr. Woodward found it also in England." In the crevices of rocks and old walls in the south and west of England, about St. Ives, in Cornwall, it appears to be found freely. It has also been met with in Devon, Somerset, Sussex,

Black Spleenwort (*Asplenium Adiantum nigrum*).

Society's Transactions. In growing the Alternate-leaved Spleenwort in the cold greenhouse, in a shady place of which, provided that it be well ventilated, it thrives best, it is well that the soil, which should be of a very light nature, such as a mixture in equal parts of sharp silver sand, sandy peat, and lime rubbish, should rise to a conical point, on the summit of which the Fern should be planted with its crown well above the surface, so as to prevent all water settling around it. The pots must be particularly well drained, with about one-third of their depth filled with crocks or broken bricks, as an excess of water is at all times fatal to it. The safest way to propagate this curious species which has not produced any variety is by division of the crowns in the early spring. The Reflexed Spleenwort, or *Asplenium refractum*, is an entirely distinct and beautiful form, a native of Scotland, from whence it has been distributed as a supposed form of *Asplenium viride*, a species to which, however, it bears

concerning its nationality may, however, be set at rest by the fact that Mr. Hudson, in the first edition of his "Flora Anglica," published during the year 1762, states that it grew then upon rocky places near Wybourn, in Westmoreland, and also that in his "Filices Britanniae," or "History of British Proper Ferns," Mr. Bolton says that this same Smooth Rock Spleenwort was found on the walls of Amersham Church, in Buckinghamshire. It has more recently been found on rocks in Wharnciffe Woods, Yorkshire; at Matlock, in Derbyshire; on a wall at Ashford, near Petersfield, in Hampshire, and on rocks near Stonehaven, in Kincardineshire. Although a British species, the Smooth Rock Spleenwort is a plant which, to be grown in perfection, requires, in common with a few others, to be cultivated as a pot plant under glass all the year round. It will be found beneficial to the plants, when potting them, to keep their crowns well above the material employed, which should be a mixture of sandy peat and broken bricks and old mortar, in which the plants should be potted firmly, with a thorough good drainage made of freshly broken bricks, into which material the roots of all Ferns, but particularly those of the small-growing kinds, appear to delight in running. Like most Ferns belonging to this section, the Smooth Rock Spleenwort is readily propagated by the division of the plants in early spring. It should be sparingly watered.

THE LANCEOLATE OR SPEAR-SHAPED SPLEENWORT (*Asplenium lanceolatum*) is another of the small-growing, but exceedingly interesting varieties of our Ferns whose distribution is particularly local, and although undoubtedly a British Fern, it is of a comparatively delicate habit, growing naturally only in peculiarly sheltered, well-drained, yet moist

Alternate Spleenwort (*Asplenium germanicum*).

Gloucestershire, in Oldbury Court Woods, and in the lanes in the neighbourhood of Stapleton, where Mr. Sweet, in his "Bristol Flora," says that "the area of this plant is no more than half a mile, occurring on the old red sandstone." It has also been found in Carnarvonshire, Denbighshire, Glamorgan-shire, Merionethshire, and Pembrokeshire, but always in small quantities compared to most other Ferns. Like a few more of its congeners of small dimensions, this interesting little plant grows well in a greenhouse shaded from the hot sun. Under such treat-

Rock Spleenwort (*Asplenium fontanum*).

ment, and provided that it be kept moderately moist, the stature of the plant is much increased and its fronds, which then attain a length of 8 inches to 10 inches, are of a beautiful dark green. The soil which suits the Lanceolate Spleenwort best is a mixture of peat, lime rubbish, bricks broken small, and leaf-mould in about equal proportions. In planting or

potting, the crown requires to be well kept above the surface of the soil. It is propagated by division in early spring, but it is a delicate operation, which requires a little more attention than it is usual to bestow on British Ferns. S. G.

Maltese way of growing Ferns.—The Maltese have a somewhat novel way of growing Ferns, that we might advantageously adopt in England. The practice is to fill a large, porous earthenware bottle with water. Place carefully all round the sides Sphagnum Moss mixed with a small amount of peaty soil, and then bind the whole with wire to the bottle. When this is done, insert small pieces of Maiden-hair Fern at regular distances apart. Then hang the bottle in a warm house, and sprinkle frequently with water to keep the Ferns in health. It is also essential to keep the bottle nearly full of water. Ornaments of this kind look well in conservatories or in rooms.—T. W.

Doryopteris ludens.—This is a very handsome and desirable warm house Fern, recently introduced by Mr. W. Bull, Chelsea. It is said to be a native of Barmah, the Philippine Islands, and also of the hills about Chittagong. The fronds are produced from a creeping, scaly rootstock, and are borne upon ebony black polished stems. The infertile fronds are the smallest, triangular or hastate in outline, the basal lobes being more or less deflexed. The foot-stalk of the fertile frond is much longer, and the frond itself is entirely different in shape, being some 6 inches across, pedately divided into long lanceolate lobes; these are thick and leathery in texture, and deep shining green in colour. The fronds are very persistent, and the effect of the two forms upon the one plant is very charming.—W. H. G.

Platzozoma microphylla.—I have received specimens of a plant (of which I enclose a portion) from my brother, who has been travelling in the north of Queensland; shall be glad if you can tell me the name of it. It is not in good condition for naming, as it appears to have neither flowers nor leaves, but all the stems are clothed with seeds as in the specimen sent. Do you think the seeds would grow? and if so, how should I sow them?—MARIAN GORDON.

* Your specimen received is a frond of a Fern which we believe is peculiar to Northern Australia. It is not in cultivation in this country, and would not appear to be a common plant in its native habitat. If the little pouched leaves contain spores, they would probably grow; at any rate, the species is so beautiful and so rare, that the attempt should be made. The leaves should be rubbed in the hand in order to disengage the spores, and the latter sown upon light yellow loam, which should be covered with a pane of glass or a small bell-glass until germination takes place, keeping the soil moist and shaded. ED.

SHORT NOTES.—FERNS.

Dicksonia antarctica (T. W. B.).—Your greenhouse is quite warm enough for the above plant; when kept in a stove, it is very subject to be attacked by thrips, which soon disfigure the fronds.—ED.

Pteris serrulata cristata compacta.—This is of a similar character to the type, but the habit is far denser, yet it is neither stiff nor formal. It grows freely, and the young fronds are of a light colour, in some instances almost white. We saw several specimens in the nursery of Mr. May, at Upper Edmonton.—T. W.

Death to slugs and other pests.—Mr. Samuel Barlow, Stakehill, near Manchester, writing to one of the agricultural journals, strongly recommends the use of superphosphate of lime as a destroyer of the Turnip fly, slugs, &c. He states that he had a field of Turnips badly infested with the fly, and he tried the experiment of dusting a few of the plants with superphosphate of lime, and found it destroyed the pest entirely. He then enlarged the area of the experiment, and had the whole field dusted with it, the result being the entire annihilation of the fly. He was also led to try the effect on some large clumps of Pansies, where slugs gathered in large numbers. The tufts were

lifted and the soil beneath them dusted with superphosphate, and thus the slugs were destroyed. Woodlice succumbed to its influence also. Mr. Barlow recommends the application of superphosphate of lime to all garden crops and plants attacked by slugs, &c., and, he remarks, the application is sure to be much more effective than dusting with powdered quicklime, which changes to carbonate of lime on exposure to the atmosphere for a few moments, and is thus rendered harmless to slugs. I found by experiment that after the superphosphate had been rained upon for ten hours, it was still able to destroy slugs. The superphosphate I employed was the ordinary 26 to 28 soluble.—R. D.

KITCHEN GARDEN.

W. WILDSMITH.

KITCHEN GARDEN NOTES.

HOEING AND WEEDING.—Now that the thinning of the various crops is completed, additional attention can be given to hoeing and weeding. To all crops not mulched, hoeing—stirring the soil—even if there are no weeds, is essential to secure the best results, and particularly so in dry, hot weather. In kitchen gardening, hand-weeding ought only to be practised where the hoe cannot be used, or in showery weather when the hoe would be worse than labour lost. By losing no opportunity of hoeing when the weather is dry, there need be no occasion to hand-weed other than in the seed rows.

WATERING.—Scarcity of labour will not admit of our doing much of this, and therefore, by deep cultivation and mulching, we strive to render the operation unnecessary. Except for such crops as Celery and Cauliflower, watering is seldom resorted to, and it is only given to these until the plants are well established; and, perhaps, to Cauliflowers and Brussels Sprouts in the form of liquid manure, when the plants are about half grown. Ridge Cucumbers, Vegetable Marrows, Tomatoes, and other ridge or frame crops are, of course, exempt from this category, as artificial watering must always be considered a necessary part of their cultivation.

EARLY BROCCOLI, SAVOYS, AND COLEWORTS.—Our first plantings of these had to be made between the rows of Potatoes, and now, to avoid damage to either Potatoes or the intermediate crops, we find it desirable to go over the ground twice a week, and throw back the haulm to prevent it smothering the winter greens. The Potatoes are early varieties, so that they will very shortly be ready for harvesting; but meanwhile no pains will be spared to keep the plants from injury. At last Peas are plentiful, and our earliest will soon be over, when the ground will at once be cleared. No digging will be done, and the ground will at once be re-cropped with early Broccoli and Savoys. The plants are quite ready for transplanting, though being on a cool north border and thin on the ground, they are not suffering from the unavoidable delay of removal to permanent quarters.

SOWING SEEDS, VARIOUS.—In prospect of an abundant supply of summer vegetables, all further sowings of summer Spinach that so quickly run to seed in dry weather, can now be dispensed with, and the ground utilised for crops of Lettuce and late supplies of dwarf French Beans and Peas. The former we have sown between rows of Celery, and the latter on recently dug ground, that was last cropped with sprouting Broccoli—perhaps the most profitable of all hardy greens. We have been gathering sprouts of this for fully three months, and we have noted it as one of our staple crops for next winter. This, together with Cottager's Kale and Brussels Sprouts, having best stood the late severe winter, will this year be grown more largely, and uncertain and tender kinds of Broccoli will be discarded. We have just made the main sowing of Endive on ground where it is to mature, and the two former sowings have been thinned to about 10 inches apart. Small Beetroot being in request,

we have sown now, and as soon as we can get early Peas off the ground, a sowing of early Nantes Carrots will be made for early winter use, to be drawn as wanted. By covering the bed with Bracken to keep out frost, it is possible to continue the supply of young Carrots all through the winter.

GENERAL WORK.—Mulch and stake Peas and runner Beans. Pinch out the tops of Broad Beans if black fly has infested them; this fly has a preference for the tops, hence pinching generally effects a clearance. If there is no black fly, topping is unnecessary, though it is sometimes done with a view to hasten the ripening of the crop. Earth up tall-haulmed kinds of Potatoes; dwarf-haulmed sorts do not need earthing unless they have been planted so near to the surface that the tubers will be exposed to light unless they are earthed up. Finish trimming up Box edgings.

MANAGEMENT OF GARDEN MEN.

EVERY gardener in England knows, or ought to know, how to manage those who are under his superintendence. To open the subject, I think a gardener should know what jobs each one of his men can do in the best style, and that job put him to, for by so doing, the work becomes a pleasure to the man rather than a toil, and ends in satisfaction to the gardener. To make my subject more clear, I will give an outline of how I manage my kitchen garden men at Burgley. Take digging for the first job under notice. I make it the practice to place say half-a-dozen men the first thing in the morning upon a plot, and it is astonishing what a large piece of ground these six will turn over before breakfast. Breakfast being over, you select the man who can hoe the best for hoeing Onions, small seeds, &c.; we use the draw hoe here, and to see the methodical way the man puts the corner of the hoe among the crops is wonderful; not a foot-print is left. The next job I call attention to is taking out Celery ridges and patting up the sides of the trenches. For this I select two men who I know will do the work to my entire satisfaction, and upon visiting them I find such is the case. Again, there is the important job of pricking out various kinds of greens, and above all the Jubilee Sprouts to be potted (never be too late). The man I select for this work is just as proud of a dozen or two two-light frames filled with early Celery, Carrots, Potatoes, Turnips, Brussels Sprouts, and Cauliflowers as the greatest foreman of the age could be over his Orchids.

Perhaps the most useful of my men is the handy man, who does the painting, glazing, and 500 other jobs, such as mending water-pots, pumps, engines, and syringes; making packing crates, boxes for cut flowers, mending wheel-barrow and garden tools. He sometimes meets with a difficulty, but I encourage him, saying, "If you cannot do the job, Jim, no man can." We (I mean Jim and I) inspect the job, and I always manage to settle the case and Jim accomplishes it. I thus manage, as it were, to surmount the difficulty—I hate difficulties. The next man under notice is the wall man, who ever since last October has on every available day been painting and nailing. We do not nail when the weather is piercingly cold; but for such weather find more pleasant work. I say the wall man, but I have two, the assistant being a stout lad. I have now five walls, all facing south, 1000 feet run, occupied with Peaches alone, the backs being well covered with Morello Cherries; these alone take up a considerable time. I may here mention that I have never seen fly so scarce and less blister upon the trees, both Peaches and Cherries looking pictures of good health; the Peach trees are young, the set is not heavy, but I can say ample.

In closing my subject, I never ask my men, either professionals or labourers, to do one pennyworth of work unless they are duly paid for the same. I know it is done more or less in many places, but to ask or expect young men (both men) to thin Grapes after working hours, unless paid for it, is an unworthy act to do. If a gardener has got more Grapes to thin than he can get done with the ordinary staff, he should either grow less or put on more hands. The rule I endeavour to carry out is to find

a smile and good word for all, and not rule with a rod of iron, but to rule as ye should wish to be ruled by. R. GILBERT.

SHORT NOTE.—KITCHEN.

Gilbert's Late White Victoria Broccoli—I have just received a fine example of the above. On unpacking, I could not say at first whether it was a Cabbage or a Broccoli—no signs of the flower—truly a late self-protecting variety. It was cooked, some preferring the green leaves to the flower: both were good, and the latter of excellent colour. The green leaves were very tender, marrow-like eating. This is well worthy of note, especially when greens run short, as too often I know happens in large families with limited kitchen gardens, or from other causes. Those who have not tried this superior Broccoli ought to do so.—STEPHEN CASTLE, West Lynn.

TREES AND SHRUBS.

W. GOLDRING.

THE ROSE ACACIA.

(ROBINIA BISPIDA.)

THE most beautiful flower of the week among trees is undoubtedly the Rose Acacia, a tree not half enough planted in this country, and, in fact, is comparatively unknown, although it is one of the oldest of cultivated trees. It possesses all the grace and elegance of the Laburnum, is as picturesque in growth, while its bloom is of a most charming rosy pink colour, which very few, if any other, trees possess. How surprising it is, then, that one may visit twenty gardens at this season and not find in one a Rose Acacia. In ordinary seasons it flowers after the Laburnums and Thorns are past, but this year it mingles with these and other earlier flowering trees. It is quite a midsummer flower, and usually it has few or no companions in bloom. It is a tree of small growth, seldom more than 10 feet or 12 feet high, and generally only about the height of a man. It has a wide-spreading head, never very densely crowded with branches, and from its bright green leafleted foliage has a light appearance. The flowers are as large as those of the garden Pea, of similar shape, and of a delicate rosy pink usually, but varying in tint from very pale to a very dark rose. The flower clusters droop like a Laburnum, but not being so long they do not hang so gracefully. There is not a more beautiful sight among trees or shrubs than a group of old Rose Acacias of various sizes, all with umbrella-like heads hung profusely with bloom. One drawback to this tree is its liability to injury by winds. The stems are naturally brittle, and, as a rule, standard plants are grafted high on stocks of the False Acacia (*R. Pseudacacia*), so that the trees are commonly broken off at the point of union.

Pernettyas in bloom.—The *Pernettyas* are worthy of notice for the beauty of their berries during the winter months. This, however, is not their only claim to recognition, as at the present time several specimens, not only of the newer varieties, but of the typical *P. mucronata*, are laden with their small Lily-of-the-Valley-like flowers. From the waxy texture of the blossoms they remain a long time in beauty, and if gathered in the shape of small sprays just as the blooms are on the point of expanding they will, if placed in water, retain their freshness for weeks. The purity of the blossoms is still further intensified by the reddish colour of the bark and the deep green of the mature foliage. There seems to be little if any difference among the many varieties from a floral point of view, yet it would be worth while for future raisers to consider this side of the question. In any case the common *P. mucronata* must be allowed to occupy a place among select flowering shrubs. Peat is by no means essential to the well-doing of these *Pernettyas*, as they will succeed in

almost any soil, provided it is free from lime and does not get baked up during the summer.—H. P.

The Chinese Crab (*Pyrus spectabilis*).—This is a highly ornamental member of the Crab family, forming a medium-sized tree, the branches of which have, when young, rather an upright tendency, but become more spreading when old. The flowers are semi-double, pale pink when fully expanded, but deep red in the bud. They are borne in great profusion, and being rather later than many other kinds in opening, generally escape any harm from late spring frosts. Another now well-known kind, by some considered a variety of the last, is the Coral-flowered Apple (*Malus floribunda*), a slender-growing tree, whose long flexible branches are now completely wreathed with pretty pink flowers. The most effective stage, however, is perhaps before the blooms expand, at which time the coral-red buds are very showy. Both of these are well worth a place in any garden, as they are very beautiful and quite distinct from each other. T.

The Laburnum.—I have a tree of the common Laburnum in my forecourt on a north aspect, that only gets the sun early in the morning and late in the evening. It is as full of bloom as can well be, and the pendent spikes are of wonderful size and colour. In these respects it contrasts in a remarkable manner with the trees, on the opposite side of the roadway, that are in the full blaze of the sun for the greater part of the day. The hotter position appears to cause the flowers to come not only smaller, but they are soon burnt by the sun, and so quickly lose their beauty. My tree also blooms later. It will be in bloom in a few days, while the trees in the full sun are almost out of flower. That the tree is an ungraceful grower there can be no doubt, and Mr. A. Mongredien states that "the tree bears the same relation to its pride of beauty during the short time it is in blossom as the peacock's serech does to its blossom." I keep the straggling branches of my specimen—which is probably twenty-five to thirty years old—cut back, and thus the tree is maintained in fairly good form.—R. D.

The Guelder Rose as a market flower.—Calling upon a Middlesex market gardener a few days ago, I found him very busy bunching sprays of the Guelder Rose, or Snowball, as they are termed in the market. The trees are subjected to a very rough-and-ready treatment; the sprays are picked off with a few blossoms to each, and one would think that the act of doing so in this rough way would prevent the tree from flowering another year, but my informant says, no. He stated that fresh growths break out just below the point where the sprays are severed from the branches, and they produce a good crop of flowers next season. He was also making up in bunches crimson and pink Peonies, and also *Scilla campanulata*, but he informed me that the Snowballs could be sold more readily than the other two. One can quite understand the French name for the Guelder Rose, *Boule de Neige*; but to how many is it known that this is a variety of a common hedge plant, whose chief beauty lies in the bright red berries with which it is adorned in autumn. The modest inflorescence of the common *Viburnum Opulus* of the hedgerows is in marked contrast to the large snowy white balls produced by its offspring; but it produces no berries, and so the price paid for its ephemeral splendour is sterility; hence it is known as *V. Opulus* var. *sterile*. It is said the species of which it is a variety was introduced from Guelders; hence its common name—the Guelder Rose.—R. D.

Sikkim Rhododendrons.—I notice in THE GARDEN June 11 (p. 527) that Mr. Bateman says he is not aware of R. Edgeworthi having flowered out of doors in England before. We have flowered it here for several years in succession, but have always found it most unsatisfactory in its growth, which is of such a straggling character, and the plant gradually becomes so very weak, that it eventually dies. One severe shock from frost seems to paralyse it to such an extent, that it has not strength to recover itself by starting from the bottom as many of the others will. It is truly a grand flower when seen in perfection, and the fragrance is most pleasant;

still I would not recommend anyone to plant it out. It is worthy of house protection, and the flowers are much finer indoors. We have tried it in all sorts of situations with like results. *R. Dalhousiae* is another good thing when on its own roots, but the buds will not stand more than about 10° of frost. We have here one plant grafted on *R. ponticum* that has never shed its buds, so far as I remember, and it has been fully exposed for twenty years, but I am sorry to say that it is declining now. It has bloomed most profusely again this year, while several plants in different situations on their own roots have had all their buds killed. Another peculiarity in grafted plants is that the flowers are much whiter than on plants on their own roots, although that may be accounted for by the variety. I should like to know if any of your correspondents have tried grafted plants elsewhere out of doors. *R. Aucklandi* has proved itself quite hardy here; no collection should be without it. I would have sent you flowers, but they are too far gone for their beauty to be seen.—R. GILL, *The Gardens, Tremough, Cornwall*.

The double Thorns.—These highly ornamental trees are among those that are flowering with great freedom this season. They are objects of great beauty in forecourt gardens in the suburbs of London just now. It is gratifying to note that in these later days a better class of tree and shrub is being planted in these gardens; and where the Mountain Ash, Acacia, large-leaved Poplars, &c., used to be found, one can now see the finer forms of *Crateagus*, Almond, double-flowered Peach, and some useful variegated trees also. Near to where I reside there are some trees of the double pink Thorn that are so full of flower, that the foliage is hidden by the density of the blossoms. Paul's double crimson is being planted, but the trees require to become good-sized specimens before they bear flowers profusely. The single crimson makes a lovely tree when covered with its bright-coloured flowers. But how cruelly it is treated in some gardens. Opposite to where I live there are two fine young specimens, but instead of being covered with blossoms just now, very few trusses of flowers are to be seen. The reason is not far to seek. At the end of the summer a jobbing gardener goes over them with a pair of shears and clips them in as close as he would a hedge of Privet. Away goes the best part of the blooming wood of the following summer, and at this season of the year when the branches should be aglow with flowers there is little but leaves. And some wonder is expressed that these Thorns do not bloom like those of their neighbours.—R. D.

SHORT NOTES.—TREES AND SHRUBS.

Magnolia fuscata.—As an instance of the vigour of our plant of this *Magnolia*, I may mention that a chaffinch has taken up its quarters in the top branches some 14 feet from the ground, and is now hatching its young, a quantity of the powerfully-scented flowers being just above its nest.—E. B.

Snowy Mespilus.—We have few more beautiful trees than this for the enrichment of our gardens in spring. We noticed it in full glory in many gardens at Feltham, and were struck with its chaste and delightful appearance when surrounded with trees of the same elegant character. It also makes a good specimen for the outskirts of a spacious lawn.—C.

Robinia inermis.—A neighbour of mine who has in his front garden some trees of this that are cut back close every year is much troubled by snails, who find their way to where the young shoots are breaking into growth and devour them. Is this an unusual occurrence? My neighbour has not been previously troubled in this way.—R. D.

Water Elder (*Viburnum Opulus*).—This is a very beautiful native shrub, quite as pretty, if not prettier, than many of the exotic shrubs now in cultivation. Of good habit and a profuse bloomer, it has a splendid effect in quiet corners or by the water. Water Elder is a good example of an English name based on a general resemblance to the true Elder.—A. H.

Double-flowered Horse Chestnut.—The double-flowered *Wistaria* has, as far as my experience of it goes, proved of little value. Of the double-flowered variety of the Horse Chestnut the same cannot be said, as the flowers are really double, open well, and remain a long time in beauty. This double-flowered Horse Chestnut is undoubtedly an acquisition, and as such is spoken highly of by Messrs. Ellwanger and Barry, Rochester, N.Y.—T.

Orange ball Tree (*Buddleia globosa*).—There is a fine specimen of this shrub flowering now at Gunnersbury House. When backed with dark-foliaged trees and shrubs, the golden yellow globose flower-heads have a rich and striking appear-

ance. In a garden at St. Margaret's, which is situated near to the sea, between Deal and Dover, the *Buddleia* thrives vigorously, notwithstanding that the soil is chalky and the position bleak. To ensure a sturdy growth and profuse display of flowers a light soil is necessary.—T. W.

ORCHIDS.

W. H. GOWER.

EUROPEAN TERRESTRIAL ORCHIDS.

THE collection of these plants shown by the Comte de Paris at the Regent's Park last week deservedly attracted considerable attention, not-

Long-bracted Orchid (*Orchis longibracteata*).

withstanding the counter attractions of the numerous examples of the showy epiphytal tropical kinds that were staged upon that occasion. The Comte de Paris has long been a de-

voted admirer and a most successful cultivator of these plants; for some years ago his garden at York House, Twickenham, was celebrated for its fine collection and for the excellent manner in which they were flowered. The extreme beauty of these choice and singular, if not showy, flowers should endear them to all genuine lovers of Nature, and especially as they commend themselves to those with limited space or the taste for the erection of glass houses, which are requisite to maintain such collections of their showy relatives as were to be seen in close proximity to them on Wednesday last. No excuse, therefore, is necessary for urging upon our readers the advisability of their culture. We propose confining our remarks for the most part to the kinds shown by the Comte de Paris, which, it was stated, had been collected from their native habitats and grown in either the open air or a cold house, the most notable amongst which were the heart-lipped *Serapias cordigera*, from the south of France and the whole Mediterranean region, with its dense spikes of bloom, delicate bracts, and large brownish purple lip; the tongue-lipped *S. lingua*, having a somewhat lax spike with a soft reddish carmine lip, stained in the centre and at the base with yellow; and a somewhat similar kind called *S. pseudo-cordigera*. Two other handsome species of this genus found in various places on the Riviera which were not shown in this collection are the long-petaled *S. longipetala* and the Butterfly Orchid, *S. papilionacea* and its variety *lingua*, which by some is considered to be a natural hybrid, having very large, velvety, reddish purple lips.

The genus *Ophrys* had numerous representatives. Conspicuous were the Saw-fly, *O. tenthredinifera*, which is one of the strongest growers of the genus, and withal one of the most profuse bloomers. Its flowers are large, and curiously marked with yellow and velvety brown. The beautiful purple *O. longicornis*, the Bumble Bee Orchid (*O. bombylifera*)—all three from the south of Spain; *O. fusca*, from the south of France.

The Spider Orchid (*O. aranifera*) from Mentone is nearly allied to our native Bee Orchid, and is one of the very earliest to appear, flowering about Christmas at Mentone. The outer portion of the flower is yellowish green; the large lip velvety brown, curiously marked on the centre with blue.

O. Speculum and its variety *luteum*, which has yellow flowers, with a conspicuous shining metallic blotch in the centre of its lip. Orchids were represented by some of our own native species, amongst which were grand spikes of the early purple Orchid, *O. mascula*, and the Spotted Hand Orchid, *O. maculata*, its spike of bloom resembling somewhat in colour that of *Saccolabium guttatum*. The Military Orchid, *O. militaris*, and its variety *O. tephrosanthos* and *O. fuscata*. Two very fine species of this genus not shown last week, but which we here figure, are *O. longibracteata* from the south of Europe, in which the sepals and petals are of a rusty brown and green. The large lip is soft purple, flaked and streaked near the margin with a deeper shade of the same colour, and white in the centre. It is one of the earliest varieties, flowering in a cold house during February and March. *O. longicalcarata*, from Algeria, is also an early flowering plant of great beauty; the sepals and petals and the spur are white, shading to lilac or purple, the lip being bright vinous red. Beside those named above, there were shown fine spikes of the pure white flowers of

Cephalanthera ensifolia, and also the yellowish green ones of the Man Orchid (*Aceras anthropophora*), &c.

We do not advise these plants to be treated as ordinary hardy plants, wet and heat being so inimical to them, an ordinary frame with the means of keeping severe frost and rain away being all that is requisite for our native species, but in order to succeed with the kinds from Southern Europe, Northern Africa, and Australia, a frame with a single row of hot-water pipes round it will be found of great advantage. The heat will not be required for forcing the plants into growth, but merely to dry up damp

Long-spurred Algerian Orchid (*Orchis longicalcarata*).

and protect from severe frosts. It must be borne in mind that the underground tubers of terrestrial Orchids only live one season; therefore every attention should be given them when growing in order to ensure their flowering the following season. After the leaves and stems have decayed water may be withheld entirely for a short time to thoroughly ripen the tubers, after which the soil should be kept in just a moderate damp condition, but not wet. Of the kinds named above, the *Serapias* and *Orchis longicornu* should be potted in a mixture of loam, leaf-mould, peat, and sand in about equal proportions, but the other kinds require loam and limestone only, whilst in all cases the drainage must be maintained in perfect working order. To make a good display at the flowering

season four or five tubers should be grown in one pot, but the ordinary system of potting in the middle must be abandoned, as the roots like to feel the pot, and therefore they should be inserted at regular intervals round the sides.

Cypripedium niveum.—This charming Lady's Slipper is flowering in several collections round London. It is one of the best of the dwarf-growing kinds, bearing with great freedom neat flowers, white, save a few purplish dots on the petals. It looks well in small pans or pots suspended in a light position in the Orchid house.—F. W.

Ionopsis utricularioides.—This is a rare, but extremely beautiful member of a small genus of which *I. paniculata* is the best known. We saw it recently in full bloom at Kew, and were struck with the surprising delicacy and beauty of the flowers, which vary somewhat in colour, but the majority are white, speckled and lightly suffused with purple. They are borne in lengthy spikes in great profusion, the plant, when suspended in a light position, having a graceful and pleasing appearance.—C.

Cow-horn Orchid (*Schomburgkia tibicinis*).—This interesting and noble Honduras species is now in bloom at Messrs. Veitch's nursery, Chelsea. The scapes are of considerable length, some nearly 5 feet, and terminated by panicles of large, handsome flowers. The waxy sepals and petals are pale rosy pink, with dark-coloured spots; the lip is pale rose, except the bold, lateral lobes, which are veined with dark brownish purple. It was discovered in Honduras by Mr. Skinner.—E.

Cœlogyne pandurata.—This plant is a native of Borneo, and bears bright apple-green and black flowers. It is said to grow naturally on branches of trees in very shady places, and mostly upon those overhanging streams or pools of water. It has generally been considered a difficult plant to manage, but probably this has arisen from its having been subjected too much to the sun's influence. There is a fine healthy plant now flowering in Mr. Measures' garden at The Woodlands, Streatham, bearing blooms nearly double the size of any we have seen produced by this species. Its peculiar colour renders it very conspicuous when grouped with light-coloured flowers. Mr. Fraser treats this plant to moderate heat, an abundant supply of water, and shades it well from the sun's rays.—W. H. G.

Vanda Amesiana.—This new and unique plant flowered in the Clapton Nursery with Messrs. Low and Co. some time ago, and is quite a distinct form both in habit of growth and also in flower. The leaves are somewhat thick and fleshy, and gradually taper to a point. The spike is erect, bearing about a dozen flowers, which at first sight remind one somewhat of the blooms of *Phalenopsis Portei*. The sepals and petals are creamy-white tinged with rose; lip rich rose colour, fading through bronze to yellow. It would appear to be a free-flowering plant, as the specimen in question is small, bearing about half-a-dozen leaves and two spikes of bloom. It was imported amongst other Orchids about three years ago, and is the only plant known to exist in Europe.—W. H. G.

SHORT NOTES.—ORCHIDS.

Oncidium auriferum.—This distinct and beautiful plant is now flowering freely at Kew. The flowers are rich golden yellow, and borne in spikes about 1 foot in length. It is one of the prettiest of all the *Oncidiums*.—T. W.

Dendrobium Farmeri aureum.—This is now in flower at Gunnersbury Park, and also the South American *Oncidium Phillipsianum*, with its gold and brown blossoms.—R. D.

Dendrobium Lowi.—This is one of the most interesting Orchids in bloom at Kew. The flowers are borne in dense racemes, and measure about 2 inches in diameter; the sepals and petals pale yellow, the base of the lip veined with crimson and fringed with reddish hairs. It is certainly not so popular as some of the members of the genus, but thoroughly deserves a place in choice collections.—C.

Viola canina.—Will any reader of THE GARDEN say if a variety of the above with pale pink or mauve flowers is known, and whether if so is it rare?—R. L. A.

CENTRAL PARK, NEW YORK.

THE Central Park contains over 800 acres, and is the park of New York. At the present time (May 27) in cool and shady places many Tulips linger. White Pottebakker as a white; *Chrysolora*, Yellow Prince, and Canary Bird, as yellow; and *Belle-Alliance*, red, are the favourite kinds, with *Duc Van Thol* as an early scarlet for edges. Large patches of red, pink, and white Moss Pink (*Phlox subulata*) are seen upon the rocks and rocky slopes; *Phlox amona*, purplish pink, and *P. stellaria*, lilac-blue, are associated with them, and have a striking effect as seen from the drives and walks. Evergreen Candytuft is a sheet of white; *Erysimum rupestre* a mat of yellow; *Aubrietias*, blue and purple and white; dwarf Thrift (*Armeria*), pale and deep pink; red Columbinæ; white and yellow Barreiworts (*Epi-medium*), and white Trilliums are used extensively in rocky places and contiguous beds, and catch the eye of every passer-by. To succeed these there are German Irises, Peonies, Columbinæ of sorts, perennial Coreopsis, Siebold's *Sedum*, Speedwells (*Veronica*) in variety, Bellflower (*Campanula*), and many others. Mantles of Stonecrop (*Sedum acre*) are also spread upon the rocks; a few weeks later they will be sheets of gold. But one of the most charming flowers now in bloom is the spring beauty (*Claytonia virginica*), which grows in great profusion among the Grass beneath some of the small growing trees near the base of moist slopes. Lily of the Valley spreads upon the sunny slopes and fills the air with fragrance; wild Hyacinths (*Scilla campanulata*), white, pink, and blue, are growing in the thinly planted shrubbery, and associated with them are snow mats of the great Stitchwort (*Stellaria Holostea*). And there are Day Lilies, Plantain Lilies, and true Lilies in abundance, and Solomon's Seal around the base of the rocks. In addition to the above, Pansies and Daisies are greatly used, and Forget-me-nots in limited quantity.

Greater quantities of bedding plants are being grown annually. Among *Pelargoniums*, Black Hawk, a golden bronze, is much liked; *Alternanthera versicolor*, *A. paronychioides major*, *A. aurea*, and *A. amona* are the favourites; *Coleus Verschaffelti* is not superseded by any crimson-leaved, nor Golden Bedder by any yellow variety; but *J. Goode*, a new variety, is being propagated very largely. *Centaurea candidissima*, *C. Clementi*, and *C. gymnocarpa*, *Ground Cypress* (*Santolina Chama-Cyparissus*) and *Gnaphalium lanatum* are the chief silvery-leaved plants. The *Acalyphæ* are prominent among tender shrubby plants; *Erythras* are isolated and grouped in little beds. Annuals comprise Golden Feather, *Globe Amaranth*, *Torenia Fournieri*, *Thunbergia*, *Vinca*, *Tropeolum*, and *Sanvitalia*.

In some of the water pools *Nelumbiums* are coming up, also seedlings of the tender Lilies that were planted in them last summer. But the old plants of the tender Lilies (*Nymphaea*, *Limnœcharis*, *Buck Bean* (*Villarsia*), *Pistia*, and the like) are still in pots and tanks in the greenhouses and sunny frames, as the water out of doors is yet too cold for them. These Lilies are grown in boxes some 4 feet or 5 feet square by 12 inches to 18 inches deep, partly filled with soil, and sunk in the ponds. By these means one can use the proper soil and plant nicely, and the boxes can be lowered or raised in the water to suit the plants, and in autumn the boxes can be brought out of the ponds and the Lilies removed to their winter pots with very little trouble and no fear of injuring the roots. Water Lilies are becoming quite a feature in the summer decoration of all prominent eastern parks and public gardens. *Nymphaea rubra* and *N. zanzibarensis* are in good bloom. *Pontederia crassipes* is also in flower. The flowers are large, bluish and pretty. I had not before seen it in bloom. Large, broad-headed trees of *Paulownia imperialis* are beginning to display their violet-blue flowers, but they are leafless still. The Snowdrop trees (*Haalesia tetraptera*), isolated and in groves, are a splendid sight, leafless, but covered with flowers. The flowering Dogwood (*Cornus florida*) is at its best, and shows to most advantage in front of larger trees and on warm, sunny slopes. The Colchican Bladder-wort (*Staphylea colchica*)

has clusters of waxy white flowers, and is an excellent showy shrub and the best of its race. The earlier *Magnolias* have done blooming. *M. Soulangeana* has a few blooms left, and *M. Lennei* a goodly crop. *Limonium trifoliatum* is in full bloom. The plant is about 7 feet high, very spiny, and well laden with large, white, fragrant flowers. We call it the hardy Orange tree, but whether it may prove hardy or not I cannot say. The specimen referred to occupies an exceptionally warm, well-sheltered spot. Bush Honeysuckles abound; among them *L. fragrantissima* is the favourite. The whitest of all white flowers is furnished by the Pearl Bush (*Exochorda grandiflora*), now blooming very freely. Isolated specimens of the common Wayfaring Tree (*Viburnum Lantana*) are handsome in themselves, and showy when associated with white flowers. Isolated specimens of *V. prunifolium* surpass in form and abundance of white flowers anything seen in our woods or by our waysides. *Forsythias* and Missouri Currants being past, *Canagana* and *Kerrias* furnish the yellow flowers among the shrubs. *Wistarias* in unusual profusion drape the rocks, cover the arbours, festoon the trees, and in several cases have climbed up into and taken full possession of some Maple trees.

In "The English Flower Garden" we find: "*Polygonum cuspidatum*, also known as *P. Sieboldi*, is a plant of sterling merit . . . and is undoubtedly one of the finest herbaceous plants in cultivation." In the Central Park it has become an almost exterminable pest. *Petasites vulgaris* is also found to be a very persistent weed.—W. FALCONER, in *American Florist*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL Scientific Committee.

Dendrobium polyphelebium.—To this plant, supposed to be a hybrid between *D. Pierardi* and *D. Parishii*, a botanical certificate was awarded on the proposal of Messrs. O'Brien and Smee. The plant was shown by Mr. R. B. White, of Ardarauch, and was described by Professor Reichenbach.

Diseased Narcissus bulbs.—Mr. W. G. Smith showed bulbs thinly covered just beneath the outer skin with small hard black bodies like Lentil seeds, and which constitute the "sclerotia" or resting stage of some fungus, probably a *Peziza*.

Heterosporium ornithogalli.—Mr. W. G. Smith exhibited foliage of a species of *Ornithogalum* blackened and destroyed by this fungus, which spreads very rapidly.

Outgrowths on roots of Peas.—Mr. W. G. Smith brought before the committee specimens of the outgrowths so common on the roots of leguminous plants, and which he attributed in this instance to nematoid worms. Dr. Masters alluded to other explanations that have been offered for these outgrowths, such as a *Myxomycetous* fungus, Bacteria, &c. Whatever be the cause, the plant does not seem to be much affected, as leguminous plants almost invariably have these swellings.

Plants exhibited.—Dr. Lowe exhibited on behalf of Mr. Loder a magnificent spike of a white-flowered *Eremurus*, supposed to be a form of *E. robustus*. It is quite hardy, and when known will "make a sensation" in gardens. A *Primrose* was also shown under the name of *P. verticillata*, but it was destitute of meal. Dr. Lowe also drew attention to a *Cattleya* in which the sepals and petals were mottled as in the variety known as *Massangeana*. A discussion took place on the subject, the general result being that the committee considered the appearance to be due to debility. Dr. Lowe also showed succulent roots on *Scilla campanulata*, similar to those now called "ephemeral" roots in *Crocuses*. The general impression is that these roots are intended as reservoirs for storing up water.

Flowers with barren flowers.—Mr. Barron forwarded examples of flowers, some having the stamens

Spreading, which set fruit, others with the stamens reflexed, and which were always barren. Mr. Henslow reported upon a microscopical examination of the two kinds, and found that the pollen was shrivelled and utterly useless in the recurved stamens. Like those which remained erect after the corolla had fallen, they burst their anthers while in bud, but as soon as the flower has lost the corolla the filaments become reflexed. On examination of the stigmas, ovaries, and ovules, nothing abnormal was revealed, so that if these flowers be dusted with the pollen from a normal kind, a spray being gathered just as the corolla is falling, and shaken over the others, the probability is that they would set fruit. Such an experiment would soon show if the pistils were unaffected or not. It appears that these barren flowers occur on rods growing side by side with fertile ones, and may occur on any variety, so what is the inherent constitutional cause of the "contabescence" of the stamens would seem to be obscure. It is discussed by Darwin (*An. and Pl. under Dom.*, ii., p. 165), but he could not suggest a cause, though some plants (*Dianthus* and *Verbascum*) thus affected grew on a dry and sterile bank. Dr. Masters called attention to the researches of Engelmann and Planchon on this subject, as well as to his own observations at Chiswick several years since. A tendency to assume a diocious condition seems to be general in all Vines, and is completely attained in the American species. Allusion was also made to corresponding phenomena in Strawberries.

Calceolaria (double).—Mr. Henslow reported upon the plant forwarded by Mr. Veitch to the last meeting. It proved to have "double flowers." The sepals varied from four to six; the ordinary corolla was present in the usual form, but within it, or protruding from it, was a mass of calceolate petals, sometimes about twelve in number, and of different sizes. There was no trace of any stamens or of a pistil whatever.

Photographs of Eucalypts, &c.—Dr. Masters showed, on behalf of M. Joly, of Paris, a series of photographs representing various species of *Eucalyptus*, *Casuarina*, &c., which were valuable as affording illustrations of the mode of growth of these trees.

Psilotum triquetrum, &c.—Dr. Masters showed, on behalf of Mr. Tokutoro Ito, a series of Japanese representations of this curious Lycopod, revealing an amount of variation quite unknown to the botanists present. From the same source also came a sheet of coloured illustrations of varieties of *Kaki* or Persimmon (*Diospyros*) cultivated in Japan.

Osmanthus ilicifolius.—Dr. Masters called attention to a peculiarity in the mode of growth of this shrub, consisting principally in the uplifting of the innermost bud-scales, which in place of falling off at once, or remaining at the base of the shoot, remain attached for a considerable period to the growing shoot, and contrast remarkably with the ordinary leaves. The superficial resemblance of this plant to a Holly was commented on, and attention called to its excellence as an Evergreen for town gardens.

Dr. Masters also showed from Mr. A. Waterer's nurseries specimens of *Acer Walli* (yellow), *A. Weihi*, a large-leaved form of *A. dasycarpum*; *Tilia eucliora*, a very dark-leaved Lime; *Fagus antartica*, the evergreen Beech of Patagonia; and other plants.

YORK FLORAL FETE.

THE floral fete which has recently taken place at York proved as fine as any that have previously been held, the classes being well filled and the exhibits of high merit. In the class for a group of ten stove and greenhouse plants in bloom and six ornamental plants, Mr. Letts, gardener to the Earl of Zetland, Richmond, Yorks, was placed first with good well grown specimens of *Azalea Duc de Nassau*; *Anthurium Scherzerianum*, *Shuttleworth's variety*; *Erica coccinea minor*, *Clerodendron Balfourii*, *Phenocoma prolifera*; and among the foliage plants there were good examples of *Croton Victoria* and *Kentia Fosteriana*. For a group occupying a space not ex-

ceeding 250 square feet, Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Darlington, and Mr. A. Webb, gardener to Mr. J. H. M. Sutton, Newark, were placed equal firsts; and Mr. McIntyre was also to the fore for a group occupying 150 square feet. For six stove and greenhouse plants Mr. Letts was first, his plants being models of good culture, and Mr. H. Johnston, gardener to Mr. J. B. Hodgkin, Darlington, followed closely. For four Crotons, Mr. McIntyre again occupied the leading position, Mr. A. Webb being second.

Pelargoniums were magnificent. Mr. Mackintosh was first in the class for twelve show varieties, having well grown plants of *Lady Isabella*, *Salmonida*, *Prince of Pelargoniums*, *Kingston Beauty*, and *Triomphe de St. Mandé*. Mr. I. Eastwood, gardener to Mrs. Tetley, Leeds, was second. The last mentioned exhibitor was first in the class for twelve zonals.

Orchids were very fine. Mr. Cypher gained the first prize of £21, staging well-flowered specimens of *Cattleya Mossiae*, *C. lobata*, *Odontoglossum vexillarium*, and other well known kinds. Mr. Cypher was also successful in several other classes.

Roses were largely represented. Messrs. Jackson and Co., Bedale, Yorks, were highly successful, taking several first places; *Duchess of Edinburgh*, *Abel Grand*, *Countess of Rosebery*, *Peach Blossom*, and *Miss Hassard* were creditably shown. For forty-eight cut Roses, Mr. H. May, Bedale, Yorkshire, was first, and he was also to the front for thirty-six and twenty-four blooms.

Fruits and vegetables were highly satisfactory considering the lateness of the season. In the class for a collection of six dishes, Mr. J. Edwards, gardener to the Duke of St. Albans, Notts, gained the first prize, which consisted of the Veitch Memorial medal and £5. Mr. McIndoe, gardener to Sir J. W. Pease, Bart., M.P., Gisborough, was a close second. Mr. McIndoe was first for a collection of eight dishes; Mr. Dawes second. Messrs. Webb offered special prizes for a collection of six kinds of vegetables, the winner of the premier award being Mr. McIndoe; Mr. Crawford, gardener to Colonel Thorpe, Newark-on-Trent, was second.

Among the miscellaneous exhibits, a group of *Clematis*, from Messrs. R. Smith & Co, Worcester, was very noteworthy. It consisted of twenty large and beautifully flowered specimens. Messrs. Kelway & Son, Langport, sent a beautiful lot of *Pyrethrums*, and Messrs. Backhouse and Sons presented cut flowers in great variety.

EXHIBITING.

THE widely spread floral exhibitions held throughout the country, especially in the midland and northern counties, are perfectly marvellous in their number and the influence they exercise. Not only do we find horticultural societies in the towns, but a very large number of villages have their flower shows also, and if they are not strong enough individually to hold one, a few villages lying close together will combine and hold their annual show. There is scarcely an important suburb of London without its horticultural society. It is a question with some whether flower shows are of much practical good. I think this depends in a large measure upon the schedule of prizes, the selection of plants, and the mode in which they are managed. When flower shows are promoted simply as a commercial speculation—as I fear many are—they prove of but little practical value, but when carried on with a view to advance gardening among allotment holders, cottagers, and amateurs, healthy competition is developed, and much good results. Still, it is a practice with some, where but little in the way of safeguards exist, to exhibit things not of their own growing. A painstaking and vigilant committee can do much in the direction of restraining such practices. I think it is always a good plan to have the exhibitors represented on a committee of management, taking care they do not unduly preponderate. Good is done by causing exhibitors to sign an entry form, in which they subscribe to the statement that the articles entered for exhibition are their real property and growth. I find on the part of men

not over-scrupulous a great dislike to make a false statement of this kind. In my own experience—now an extensive one—I have found members of committee leading offenders in this respect, and then it is difficult to deal with culprits. If the managers of flower shows will make a summary example of any exhibitors guilty of dishonest showing, this form of cheating will be considerably reduced, if not altogether stamped out.

R. D.

Snake millipedes.—I have by this post forwarded to you a box containing a centipede of some description, and shall be much obliged if you will kindly through your paper let me know if it is an insect injurious to Orchids, as I have found it only upon two plants which I lately purchased, six on one and two on the other. It only appears at night, and I believe, feeds upon the young roots, and should this be the case, no doubt Orchid growers, especially amateurs, will be pleased if you will kindly say what it is.—Geo. Wood, *Grafton House, Brandon*.

* * * The creature forwarded is one of the snake millipedes, a species of *Julus*, but which I cannot say, as it was literally smashed to powder. The snake millipedes are decidedly injurious to the roots of plants; the best way of catching them short of uprooting the plants is to cut Potatoes in halves and to slightly scoop them out, and lay them near the roots of the plant, so that the millipedes can creep under them. Examine these traps in the morning. Any insecticide which would kill them would probably injure the plants.—G. S. S.

Saw-flies.—I herewith send you a specimen of a fly (an Italian one). It appears to hover about Roses, and I fancy may deposit eggs on the stems. After the eggs are hatched the grubs eat their way into the stems. I should be much obliged for information as to getting rid of the pest.—M. SCOTT.

* * * The flies forwarded are saw-flies, one of the *Tenthredinidae*; several members of this family attack Roses, their grubs devour the leaves, and some burrow in the stems. Kill the grubs or flies wherever they can be found; if the former are very abundant, syringe the bushes with soft soap or tobacco water.—G. S. S.

Cork bark for edging.—Having a lot of old virgin cork lying about, it occurred to me that it might be utilised for an edging to walks. I embedded the pieces in the soil, leaving about 3 inches out of the ground. I rather like the appearance of it, as it does not look so formal as tiles, and will, of course, last a number of years. I have never seen cork bark mentioned as suitable for this purpose.—J. C. B.

Mode of packing cut flowers.—Will some of your readers kindly give some instructions as to the best way of sending cut flowers, best time of cutting them, and best method of packing? Mine always wither at once; those bought at shops do not last long.—F. J. RADCLIFFE.

We are requested to mention that in the official list of awards of the recent flower show at the Crystal Palace, the award of a first-class certificate to Messrs. J. Curter and Co. for their Jubilee Mimulus was inadvertently omitted.

A list of the awards of the fruit and floral committees of the Royal Horticultural Society from February, 1884, to May, 1887, has been sent to us, and, we understand, may be obtained at the South Kensington office of the society.

We are asked to state that a special general meeting of the Fellows of the Royal Horticultural Society will be held at 3 p.m. on Tuesday, June 28, in the conservatory, to consider the results of the negotiations and inquiries which have been made by the council as to the future maintenance and housing of the society. N.B.—Entrance N.E. Orchard House, Exhibition Road, South Kensington, S.W.

Names of plants.—*Corona*.—1, *Oncidium crispum*; 2, *Thunia Marshalli*; 3 and 4, *Cattleya Mossiae* vars., lips too bruised to identify; 5, *Andromeda japonica*.—*G. and J. Lane*.—1, *Lilium davuricum*; 2, Rose, probably a variety of *Rosa alba*; 4, *Lilium japonicum*.—*Anna*—*Cuedia coccinea*.—*F. M.*—The yellow variety is *Iris juncea*; other not known.—*J. Boller*.—*Eurybia Gumi*—*F. E. (Ladysmerry)*.—1, a Saxifraga, but flowers all gone; 2, *America vulgaris*; 3, *Corchorus japonicus*; 4, *Scilla nutans*; 5, *Asperula odorata* (Woodruff); 6, *Saxifraga tribracteata*.—*Bichter*.—*Scilla nutans*.—*Miss Robertson, Ipswich*.—*Ceanothus azureus*, *Oncidium spheclatum*, *Banksian Rose*.—*J. D. M.*.—1, *Cystopteris montana*; 2, specimen insufficient; 3, *Gnaphalium oleum*; 4, *Papaver bracteatum*; 5, flower shrivelled; Fern, *Plymatodes Billiarderi*.—*R. L. A.*—1, *Andromeda axillaria*; 2, *Cytisus Adamii*.

WOODS & FORESTS.

"YORKSHIREMAN."

FORESTRY NOTES.

FENCES.—I do not undertake to determine whether it be creditable to "the bulk of the people," as Mr. Yeo puts it, or not, that they do not all know the difference between riven and sawn stakes, but I am aware that there are some people who do not know this; hence my pointing the fact out. If it is well known that riven stakes are best, how comes it that so many sawn ones are used? On estates near here there are miles of these, and they are common everywhere. At one large saw-mill belonging to a timber merchant thousands are sold to farmers every year. It is facts I go by, not supposition. You can hardly travel by train anywhere without seeing fences of sawn stakes. As to the staying power of our post and wire fences, which Mr. Yeo says "he has little faith in if they exceed a height of from 3 feet to 4 feet when subjected to lateral pressure," I have only to say that he has clearly never tried them. I can show him fences of this sort 3 feet 9 inches high and posts 9 inches asunder without a stay for about 100 yards, and I will give him every opportunity of testing them by lateral pressure, so that he can judge for himself. We have scores of miles of plantation fences, I daresay, and I sorely grudge the expense of keeping them in order. In this part of Yorkshire, and other counties as well, I have noticed that the Quick hedges, almost without exception, have cost more than their worth to raise and keep good round plantations, and that they are generally dead, neglected, or useless, and as forestry on any estate must be managed economically to pay, I cast about in my own mind, some time ago, for a substitute for these and other wood fences generally in use, and pronounced in favour of the posts and wire. The wire is cheap and lasts a long while; the Oak stakes we can rive on wet days from dead and often sap rotten Oak, using the heart-wood mainly, which lasts longest, and the fences are the best we have tried. The lateral pressure suggested by Mr. Yeo is a myth. We have hundreds of cattle and horses grazing in the parks here, and I observe that the mere sight of a slim fence turns them. They never attempt to knock down a fence, or jump over one unless forced, and the only damage done is to the posts, against which the animals rub themselves.

PLANTING WASTE LAND. There is much waste land about here fit for no other purpose than planting, but where not planted, let in with farm lands at a merely nominal rent. One large tract, however, with which I am familiar, and which is not only unfit for agricultural purposes, but almost impassable in some places, being poor, precipitous and rocky, has produced trees for many generations, and has been planted and cared for according to the times. I cannot say what this ground may have produced previously, but during the last forty years probably at least £60,000 worth of timber has been sold from it, and its present valuation will come to about £40,000. It is one of the roughest pieces of land in England, and fit for nothing but tree-growing, and the surprising thing about it is that such poor high-lying ground should have produced good and saleable timber so long that it is likely to continue doing so, the young plantations of other kinds of trees planted on the cleared ground growing away as vigorously as if they were on virgin land. It is examples of this kind that cause us to treat with doubt the recommendations of some foresters to go to

so much expense to prepare ground for planting. All round here is a hilly country; wherever the rough, rocky slopes have been planted, the trees have done well and become very valuable. Foresters have quite enough to do at present to utilise waste land without troubling their heads about the comparative merits of timber *versus* corn culture. That good timber can be grown on ground where nothing else will thrive properly can be proved.

BEST SITUATIONS FOR TIMBER.—Whether it be hard or soft woods, Firs or Oaks, the tallest and straightest and most bulky timber is produced in the shortest time on steep slopes and ravines, and as such land is usually more unfit for farming purposes than the tops of the hills, it follows that they are the best places to plant with trees. There is hardly an exception to this rule; the length and straightness of the trees are remarkable. The soil being usually well drained in such places of fair depth, and shelter being afforded from cold winds, the plantations make rapid progress, and come to maturity in a reasonable time. It is sometimes desirable to plant exposed ridges for the sake of shelter, but these do not produce timber. Miles of "back-bones" of spurs of the Pennine range have been planted here in times past, and the difference between the timber on these spots and that close by, in the gorges and ravines, as regards bulk is apparent to the most casual observer. On the hill-tops the trees never get above the size of scrub at the margins of the plantations, and in the centre they are comparatively small, and where from gales spots have been thinned out, those left have quickly succumbed, leaving large gaps. The shelter afforded by these exposed plantations to the adjoining land is, however, undoubted. Some sixty or seventy years ago an enterprising landlord planted every exposed ridge on his extensive estate, and the effects are now visible in the better crops from the land. The timber crop over the whole area is, however, not worth much, and cannot be spared.

PLANTING FOR UTILITY AND ORNAMENT.—"W. B." speaks of doing this by filling the spaces under and between the timber trees with Hollies and other kinds of underwood, by which plan he can ensure a permanent undergrowth of evergreen or deciduous trees and shrubs with the most picturesque and profitable forest trees, instead of those unsightly naked plantations open at the bottom with nearly valueless timber trees so frequently to be seen, &c. I have myself seen abundant and healthy underwood of ornamental trees and shrubs in timber plantations, but never where the timber trees grew as thickly as they ought to do to make good timber and pay. My experience is that an unbroken canopy of foliage overhead nearly kills everything under it, even to the Grass; hence where underwood has to be permanently preserved, proprietors must do so at a sacrifice of timber crop and decide accordingly. As to plantations open at the bottom because of the trunks being bare—being valueless, the contrary is just the fact. Underwood will grow and live under the partial shade of other trees, but it must have a considerable amount of sunlight as well as other vegetation, and the picture drawn by "W. B." cannot be produced in timber plantations, but may be produced in the home woods where both the timber trees and the underwood are intended to remain. We are familiar with the best underwood-furnished woods in England, where the underwood consists of Hollies, Yews, Box, and Rhododendrons, &c., but the deciduous timber trees are thin on the ground, with bunchy, useless tops, owing to the room found for the Ever-

greens, &c., every one of which occupies the place of a timber tree, and none of these left can be spared. This is not timber growing.

SPRUCE HEDGES.

THE common Yew, as is well known, makes one of the most ornamental of hedges, but it grows slowly, and ought never to be planted in any situation where stock of any kind is likely to obtain access to it. On the other hand, the Spruce grows rapidly, and with proper attention proves little inferior to the Yew as regards appearance, and quite equal to it for affording shelter. The common Beech tree is also very useful for this purpose, as when kept in the form of a hedge it retains its old leaves until the young ones are about ready to take their place. In some parts of Norfolk and Suffolk, where the land is so light and poor that Quick or common Whitethorn, which is generally employed for hedges, refuses to grow upon it, the common Scotch Fir is frequently used for the purpose, and generally answers well, but in the course of a few years the lower branches are apt to die off, a fault not possessed by the Spruce. In the neighbourhood of Bury St. Edmunds there are hedges formed of Spruce some 6 feet or 7 feet high, and from fifteen to twenty years old, which at a short distance off one would think were Yew hedges. The soil where Spruce is intended to be planted should be prepared by being deeply dug or trenched, and the trees may be put in any time between the beginning of October and that of March, but the first-named month is the best. The plants should be healthy, young and well furnished, *z. e.*, plants which have been once or twice transplanted, and that have retained their lower branches, which will not be the case if they have been allowed to become crowded too long in nursery beds. They should be some 2½ feet or 3 feet in height, and should be planted 2 feet from each other; but if the plants are larger, this distance may be increased. But little attention will be required the first year after planting beyond freeing them from weeds, and as soon as growth commences, say towards the end of April, the hedge shears should be passed along each side so as to shorten the side shoots, and to some extent give form to the hedge. But the top or leading shoots should not be interfered with until they have attained the desired height, when they should be stopped, an operation which will induce the lower part to thicken or fill up; and at first the width should not be allowed to greatly exceed 2 feet, as the hedge, as it becomes older, will to some extent unavoidably increase in width. The main stem of the Spruce being fairly strong, the hedge may be allowed to grow to any desired height, and it may also be allowed to assume any desired form, such as wide at the bottom and tapering towards the top, or in what is known as the hog's-mané form; or it may be made, as it were, to form a dark green wall of any reasonable height, and exactly the same width at the top as at the bottom. The latter form is certainly the most ornamental. Such hedges must be annually clipped with the ordinary hedge shears, an operation which should be performed in August, or, if great neatness is desired, twice in the season, say in July and October. P. G.

Garden gates and doors.—The fallacy of using foreign wood so extensively for garden gates and doors is being, I believe, gradually exploded. Take the case of entrance gates. Instead of being made of good sound British Oak, they are often constructed of foreign deal. As a kind of compromise, the wood is occasionally grained to imitate Oak. Now, my notion of an entrance gate is that it should be what it pretends to be, and the proper material is British Oak. In entrance gates wood and iron can be blended to advantage, as strength and durability are gained without sacrificing the proper degree of lightness in design. The posts, of course, should be of Oak, and the rails and brace of the same material, whilst the upright rods or bars should be of iron. When the Oak is thoroughly good and varnished to show the grain, and the iron painted so as to nearly

resemble natural colour. I think we have the perfection of an entrance gate. Everyone can see of what it is composed and draw their conclusions accordingly. In the case of gates which are less prominent, a greater latitude is permissible, but on the whole, although the first cost may be somewhat greater, there is nothing better than Oak. For rails and poles Larch probably comes next. With doors as with gates, at least in every case where they are exposed to the weather, Oak should always be employed for the posts. The construction of the door itself will depend somewhat upon its size and situation. I know of doors forming the exits and entrances in a gentleman's garden which are made of Scotch Fir, and have probably been in use for a generation. As regards appearance they are as sound as when first made. I should not have suspected what the wood was had I not seen the gates when the paint was in course of removal for a new coating. The wood probably was thoroughly seasoned and first painted when dry. Owing to the comparative ease with which a door of this class is repaired, it is less important than in the case of gates that the most lasting material should be used. For this reason, and also on account of its lightness, wood of the Fir is mostly used for the boarding, and tough hard wood such as Elm for the ledges or framework.—D. J. YEO.

SEASIDE PLANTING.

NONE but those who have been engaged in forming plantations or pleasure grounds on an exposed sea-coast can form any idea of the difficulties to be encountered in carrying out that kind of work. My experience, which has been considerable, may therefore aid others who have work of that character to perform. The principal evils which one has to contend with in seaside planting are the saline particles which are carried by the wind and deposited with such persistent force on the leaves and tender shoots of trees and shrubs planted near the seaboard, as to cause them to burn and wither away. This is more particularly the case when the plants are young and have just been transplanted from the sheltered rows of the nursery garden and other places, where they have not been exposed to the full force of the south-west or other gales that come laden with salt from the ocean. Another evil, nearly as great, is the fact that the young trees and plants become loosened through wind-waving, unless they are well staked, leaving often a large hole near the neck or collar, in which water rests, and causes the bark at that point and the roots to decay. Firm planting and staking are great points in the management of young plantations near the seaside.

PREPARATION OF SOIL.—Everyone who has had any experience in planting knows how necessary it is to deeply dig or trench the ground; but this in some instances can be wrongly carried out. Wherever there is a subsoil of stiff clay, or poor binding loam, I hold it to be wrong to throw the good top spit into the bottom of the trench, and to bring the sour clay or poor loam to the top. Roots make no progress in such sterile soil, and the tops have no opportunity of making a vigorous start. Moreover, I have often seen these kinds of soil run together, and set as firmly as cement for some inches deep on the surface, so as to be impervious to air or rain, and the young roots taken from the well-prepared soil of nurseries refuse for some time to feed on the sour poor soil in which they find themselves. In all cases in which the soil is as I have just described, it is preferable to trench, so that the best material can be kept on the top. If the second spit of soil is equal, or nearly so, in quality to the top soil, trenching should be performed in the ordinary manner of casting the first spit into the bottom of the trench and the lower one on the top, this being by far the quickest way, and in some instances, where the under spit is composed of sandy, poor loam, I would bring it to the top, as this kind of soil speedily settles with a few showers round the base of the young trees, without baking or being impervious to rainfall, as the soils I have before mentioned are. All heavy clayey soils should be thoroughly drained previous to being trenched and

planted; the draining can be done by means of open drains or ditches in ordinary plantations. Spaces for open drains should be left until the trenching and planting are done, when they can be carefully thrown out, with smooth sloping sides, and the surplus soil cast among the young plants. I prefer 4-inch common socket drain-pipes, and, if obtainable, I would put some common rubble as a slight covering to the pipes, and turn a turf sod upside down on the top of the rubble. If the latter cannot be obtained, place the turf as above mentioned on the drain-pipes. I think it is always best to allow the land to have some days to settle after trenching previous to putting in the plants, and if a good heavy shower has taken place between the time of trenching and planting, so much the better for the young trees. In chalky and stiff hard lands I would, if labour could be afforded, trench 3 feet deep.

SELECTION OF SHRUBS AND TREES.—Among forest trees the Elm stands in the foremost rank, owing to the way in which it manages to grow aloft and spread its ponderous limbs direct in the teeth of the wind. On the south coast, in many neighbourhoods, are found some magnificent examples of Elms growing in most exposed situations. The Sycamore likewise thrives well near the sea, and, owing to its rapid growth, is also a valuable tree. Oak, Birch, Willows, and Poplars, Ash, and in fact every kind of deciduous tree, may be used in mixed plantations near the sea, for the sake of variety of foliage and expression; but the two first named are the most certain. It is, however, not deciduous trees that are the greatest sufferers from the salt spray. Evergreen trees and shrubs are the most injured, and many, particularly Conifers, cannot exist at all within the salt line. Fortunately, however, there are a goodly number that do withstand the sea breeze, and, with careful judicious grouping and planting, produce a good effect where other things would fail. The following is a list of such as I have tried and know will succeed, viz.: *Pinus austriaca*, a Conifer which grows rapidly and affords good shelter. I have found this Pine to resist the effects of the salt, and to grow in the most exposed situations, even in the form of single trees, as well as in avenues, having no shelter whatever. It succeeds best planted when about 18 inches or 2 feet in height. I have often lifted it when 6 feet and 8 feet in height with success. The following Pines will also grow near the sea, if not in too exposed situations, viz., *Pinus Cembra*, *Pinus insignis*, *Pinaster*, the Corsican Pine, and the Aleppo Pine. The *Pinus sylvestris*, or Scotch Fir, after it has been planted some time, resists the salt well, but I have had young plants of it, fresh from nursery beds, so injured by salt, that many of them died. Among the *Piceas* I found the following to do well, viz., *Picea lasiocarpa*, *P. nobilis*, *P. Nordmanniana*, *P. Pinapo*, and *P. grandis*. Of the Fir tribe, I have found *Abies canadensis*, *Douglasii*, *Menziesii*, *Claibrasiliana*, and *pygmaea* all to have great power of resistance as regards sea breezes. Young plants when first exposed, particularly if obtained from inland nurseries, sometimes suffer. I would recommend everyone who has planting to do by the sea to obtain the plants near at hand, and from the most exposed nurseries they can find. In continuing my list of plants and trees that will succeed well under ordinary care I must not omit *Araucaria imbricata*, which is one of the very best for the purpose, and one that bears transplanting well, even when nearly 20 feet in height. This *Araucaria* will grow almost close to the edge of the sea. Another class of useful trees for seaside planting are the *Cypresses*, of which I found the following do well, viz., *Cupressus Lambertiana* and *macrocarpa*, the latter having quite a notoriety as a seaside plant, which on the south coast is fully borne out by the many fine examples of it to be met with. In a garden at Eastbourne I saw a fine example of this *Cypress* upwards of 50 feet in height, and about the same in spread of the branches. I planted some fine trees of *Cupressus Lawsoniana* in very exposed situations, where they stood many a trying breeze, but they were not at all injured by the salt. I also found *Thuopsis borealis* and many of the *Thujas* bear exposure well, as did also *Fitzroya patagonica* and

several of the *Junipers* and *Yews*. Among evergreen trees and shrubs, the Evergreen Oak (*Quercus ilex*), *Hollies*, *Euonymus*, *Phillyreas*, *Bays*, *Portugal* and common *Laurels*, *Laurustinus*, *Arbutus*, *Erica* *codonoides* and *mediterranea*, and *Rhododendrons*, if only slightly sheltered, also do well. In fact, there are many other well-known trees and shrubs that bear almost any amount of exposure to the sea breeze. Among these I may mention the *Tamarisk*, which grows near the seashore everywhere. In St. Michael's, in the Azores, *Pittosporum undulatum* and *Tobira* grow down to the edge of the sea, and *Camellias* may be found only a few hundred feet away from it. The common green and silver-striped *Euonymuses* are the best plants with which I am acquainted for protection to borders of low tender shrubs. Their rapid, compact, and sturdy habit of growth renders them almost as impervious to wind as a brick wall; consequently, when planted, either as a hedgerow or in broken lines, they form excellent nurses and protectors to the more tender plants. I have never found the *Euonymus* to be injured by salt spray, though I have seen it growing close to the sea. I have known it to grow from 18 inches high to the height of 6 feet, 7 feet, and 8 feet in a few years. For forming masses on embankments I prefer it to the common *Laurel*. It bears cutting in any shape, and is a plant admirably adapted for forming divisions between small properties. No one, therefore, need despair of making gardens and plantations near the sea, with so much material from which to choose, if they have only good soil, and will trench, plant firmly and thick, and by all means stake young trees for a year or two. By planting the Austrian Fir in belts 4 feet or 5 feet deep round the outer edge of plantations, they speedily form a thick screen, and shelter the less hardy trees. In narrow and exposed borders of ornamental shrubs an excellent screen or nurse can be made thus: Drive some stakes firmly into the ground about 4 feet apart, interlace them with wattles, and draw or pack them firmly with green *Furze*. This will afford protection for two winters, by which time the trees and shrubs will have become established, and will protect one another.

TIME OF PLANTING.—There are a great many opinions as to the proper time to plant trees and shrubs, or, perhaps, I should say, as to the different times at which they may be planted. Some say, "plant at any time," and this may succeed occasionally. But when one has forty acres or fifty acres of plantations to put in, midsummer is not the time one would choose for the operation, even if supplied with hydrants and similar appliances. My experience points to early spring as the best time for seaside planting. Trees and shrubs planted in the early autumn are subjected to the whole of the winter's surly blast, which, in addition to the singeing they get from the salt spray, robs them of more than half their leaves. I am now alluding to situations very much exposed. With the shelter of a hill or of strong belts of plantation, I would plant in October rather than in spring, particularly if I were sure that the winter would be open. I have, however, planted young Austrian and Scotch Firs from the same nursery both in autumn and in early spring, and have found the spring-planted ones to succeed infinitely better than those put in in autumn, which got burnt so brown with salt spray as to be to all appearance dead, and, in fact, many of them were; whilst the spring-planted trees rarely or never turned a leaf, and failures among them were rare. P. W.

Destroying tree butts.—The following method is recommended of getting rid of the stumps and roots of timber in cases where grubbing-up is not considered desirable: In the autumn bore a hole 1 inch or 1½ inches in diameter, according to the girth of the stump, vertically in the centre of the latter, and 18 inches deep. Put in 1 oz. or 1½ ozs. of saltpetre; fill the hole with water, and plug it close. In the ensuing spring take out the plug, and pour in half a gill of kerosene oil, and ignite it. The stump will smoulder away, without blazing, to the very extremities of the roots, leaving nothing but ashes.

No. 815. SATURDAY, July 2, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BEAUTIFUL SINGLE POPPIES.

I SEND you a small handful of my Poppies. I exhibited a few at the Royal Horticultural show on Tuesday, and they were greatly admired.

I remember very similar flowers when I was a boy, five-and-thirty years ago, but I have never seen them since, nor had anyone at South Kensington seen such till I exhibited them there last year.

Their history is one of simple perseverance. In 1879, when I first came here, there was, in the wild part of the garden, a stray common field Poppy (*P. Rhæas*). One blossom of it showed a narrow white edge. I marked this, and saved the seed-capsule and sowed, getting in 1880 several pale red flowers and a few white margined. The best of these were again selected, the bad ones being ruthlessly pulled up. In 1881 I had distinctly advanced, and so have until now, when they appear to be perfect; indeed I am a little fearful for them, as they appear to be developing a tendency to go double, which (in my opinion) altogether spoils them. I have lots of doubles come similar in appearance to that figured in *THE GARDEN* last week, but I pull them up at once for fear of infection to the others.

I also always destroy any plant showing a sign of black in petals or stamens, or even anthers. In this lies the great difference between mine and Mr. Geo. Paul's. Often you meet with a really lovely flower, but it has black in it somewhere, and if left will infect all the rest and cause a muddy, blood-coloured progeny. Mr. Paul has not the heart to destroy these black-eyed beauties; I have no hesitation, however lovely. In mine you will observe the exquisite brightness and clearness of colour and tone. I now get not more, I think, than 1 per cent. of rogues, *i.e.*, "blackies," and I do not suppose I shall ever reduce the number below that—only, if they are to be kept pure, they require constant early morning attention to banish every rogue as soon as, or even before, he expands in villany.

You will observe one blossom which is white with a coloured edge, and one or two flaked flowers; these (though not so lovely as the pale pink with white edge) are my latest arrivals of variation save a marbled one, which, however, has not a bloom open to-day.

W. WILKS.

* * * Although Poppies do not travel so well as most flowers, the blooms sent, on the second day after their arrival, display a purity and novelty of tone quite charming to see—lovely pink and flesh colours, with white petals inside sometimes. The most refined and

charming flowers we have seen for many a day, and all forms of our common English field Poppy.—*Ed.*

ENGLISH NAMES FOR ENGLISH-SPEAKING PEOPLE.

TO THE EDITOR OF THE GARDEN.

SIR,—To a certain extent I sympathise with both sides. I fully sympathise with your endeavour to popularise our favourite plants, but I cannot think that the plan you have adopted will in any way help forward that good object. A plant becomes popular because it is beautiful, or because it is easily cultivated. Its name is of no consequence in either direction. It will not fail to win popularity because it has an ugly or a learned name, nor will it win popularity because it has a simple English name; nor do I think your new names make the plants more easily distinguished. For myself, I can safely state the contrary. *THE GARDEN* is now to me a weekly puzzle. I often do not know what plants are meant, and I am sure many must be in the same position as myself. [*Mr. Ellacombe may now have some idea of the feelings of people who have been talked to in an unknown tongue for many years.*—*Ed.*] We want an interpreter.

You object to Latin names, but leave the poor plants to themselves, and if they are worth anything the Latin names will not hurt them. What are you going to do with Rose, Tulip, Violet, Anemone, Cyclamen, Hyacinth, Cypress, Melon, Asparagus, Thyme, and hundreds of others that are pure Greek and Latin names, which have adapted themselves to their localities, and have become Anglicised, and have certainly not stood in the way of the popularity of the plants? [*Canon Ellacombe cannot suppose that anybody wants to abolish our best English names. He mentions pure English names here. Whatever they were once they are English now; but, in addition to these, we said we should keep the good Latin names.*—*Ed.*] Indeed, in many cases the classical names have taken the place of the common English names. Nobody now talks of Sowbread; we prefer the Greek Cyclamen. Nobody talks of Saffron, once the common name of all Crocuses and Colchicums. We prefer the Greek Crocus.

You mention two new names that you propose adopting. I object to both. Tiarella is to be the Foam Flower, but which Tiarella? There are several in cultivation, and certainly the name (which does not seem to me to be very applicable to any) is quite inapplicable to some. The plant already has an English name—the Mitre plant—which has the advantage of connecting together the English and Latin names (Mitre and Tiara) and of directing attention to the peculiar seed-vessel. [*A good English name need do none of these things.*—*Ed.*] Then the Saxifrage family is to be called Rockfoil, which does not seem to me as excellent as it does to you. It is a hybrid word, half English and half Latin, after the manner of trade advertisements; and why is a new name wanted? Saxifrage has become completely naturalised, and if you are going to apply the new name to all the family, what is to become of London Pride, None so Pretty, and other such names, which I certainly will not give up for Rockfoil? [*To adopt the name Rockfoil for the family in no way interferes with a good old name like London Pride. Saxifrage is very far from being "completely naturalised."*—*Ed.*]

But, as a matter of fact, have your laudable endeavours met with success? Have you thoroughly established one new name beyond the pages of *THE GARDEN*? I think not. One of

the best of the proposed names was Plantain Lily (two Latin words) for the Funkia. But in all my intercourse with gardeners I do not remember to have heard that name as the common name for the plant. Nor have I ever heard the Echiochorda called the Pearl Bush; its common name is Spiræa. [*Spiræa is the Latin name of a genus, and as an English name for Echiochorda wrong in all ways. The true Spiræa has a good English name of its own—Meadow Sweet.*—*Ed.*]

The fact is, that popular names cannot be made to order. They spring up no one knows how, and establish themselves by their own vital force, or they die at once. You cannot force a name, and you cannot kill one; and Horace's rule still holds good:—

Multi renascuntur que jam cecidere, cadentque
Que nunc sunt in honore vocabula, si volet usus,
Quem penes arbitrium est et jus et norma loquendi.

I must apologise for writing at such length, but I must add that I do not for a moment dispute your full right to coin as many new names as you think desirable. I only protest against being compelled to accept the new coinage as the only current coin, though I may also think that no new coinage is necessary. I also protest against being called a pedant because I prefer the old coinage. There is often less pedantry in using a well-recognised word (in whatever language it may be found) than in insisting on a new one merely because it is in English.—HENRY N. ELLACOMBE, *Bitton Vicarage, Gloucestershire.*

* * * I am hopeless, and said so long ago, but I print these words lest even one person should suppose there is anything in the "reasons" urged against English names for plants. Canon Ellacombe contemplates the subject wholly from the standpoint of an educated man, who has all his life been familiar with the meaning of the Latin names of plants. His (bigoted) reverence for these will not let him take any account of the existing thousands of plant-lovers who know nothing whatever of Latin, or of the multitudes yet unborn who will live and die in the same predicament. "I do not want English names, therefore no one else does," is the logic of one who has lived all his days in the sound of Latin names for plants. We cannot accuse him of altruism! I will now say a few plain words as to points raised in his note before again going on my way regardless.

1. Mr. Ellacombe says "*a name is of no consequence*" in making a beautiful plant popular. Now, long ugly names are distinctly a real difficulty in the way of a plant being known. What is a cottager, who understands what is meant by Musk, Snapdragon, and Marigold, to make of such names as *Oxyura chrysanthemoides* or *Calliethra platyglossa*, or *Platystemon californicum*, all good things that might be grown in any cottage garden? I was in a cottage garden yesterday, and asked the woman what she called the flowers. London Pride, Double Buttercup, Candytuft, Rocket Snapdragon—only one she had no name for, an autumn plant half grown. I told her it was the great Ox-eye Daisy. I wonder what she would have made of *Pyrethrum uliginosum*?

2. "*What are you going to do with Rose, &c.*" To suppose that people who crave for such names as Rose and Violet and Thyme

are going to abolish these is really too much even from an opponent of English names. These are anglicised, *not* "pure" Greek and Latin. Then names—Rose, Tulip, &c.—directly derived from Latin are as good English as half the words in the good Canon's letter that have the same parentage. Many everyday words now English are absolute Latin, not Latin anglicised, like the plant names he quotes—*opera*, *circus*, *omnibus*—but these none the less are now English.

3. "Have you thoroughly established one name beyond the pages of THE GARDEN?" It is not a question of the few names that in the interests of decency we of THE GARDEN have tried to create for pretty flowers, as, for example, Plantain Lily. There is scarcely a beautiful race of flowers of the old day that had not a pretty English name—alas! often driven out of use by the so-called scientific term. When I came to London there was only one nursery that sold any hardy flowers. The Royal Gardens at Kew were rank with bedding-out, and even there the flowers of the northern world were not considered fit to take any part in its flower gardening. The Botanic Garden in the Regent's Park was like the Marylebone Cemetery, with names written up and down instead of across. I wrote to Syon House for some white Lilies; the gardener said I was too late; the last had been burnt with the rubbish a few days before. Apart altogether from THE GARDEN, I now speak on a moderate average to over 150,000 persons every week about hardy flowers by English names where possible. Strange to say, too, people like it. No doubt Canon Ellacombe will think it sad. I cannot even say that I am at the end of my evil course. Without waiting for the end, however, I may, without presumption, I hope, say that I have established many names "beyond the pages of THE GARDEN."

4. "Popular names cannot be made to order." What of Paris Daisy, a new name adopted by trade, amateurs, and everybody? The wish is father to the thought here. Even Mr. Ruskin's Rockfoil is distasteful to Canon Ellacombe. The name will live as long as the English tongue, and that means long after the present modes of teaching botany. Botanists having given plants ridiculous appellations for many years, we are now told popular names cannot be created. Happily, thousands exist. Every day we see new inventions for which English names are found, but we are not, forsooth! to create names for new flowers. It would not please the botanic gardener, who has always been so full of tenderness for us and talked to us in such pretty ways!

Canon Ellacombe does not even see that the question is one for all, even for children. He objects to being called a pedant, and quotes "Horace" in a gardening paper! He cannot see away from his own correct labels. If he should ever repent and help me with a good English name, I will be grateful, and print it, but I cannot waste space with such "reasons" as he gives against our English

names, poor though some may be. We do not even wish to rob him of the use of his Latin, as he supposes. We want English names for flowers for English-speaking people, and any space we can give to the matter for the future will be for those who help us to get them. We, if anything, err too much in the use of Latin names ourselves. The name Flag, for example, is a beautiful English name which we have too long forgotten.

W. R.

FLOWERS IN THE HOUSE.

Under this head we propose, during the present season of flowers, to notice things, from whatever department, that are pretty and useful for the house.

THRIFT (Armeria).—I send you for your table Armeria cephalotes alba and the pink Armeria grandiflora.—C. M. OWEN.

ROSE MALMAISON AND FORGET-ME-NOT.—A beautiful thing just now is a large bowl of good old Souvenir de la Malmaison mixed with the true Forget-me-not.

THE SMOOTH ALUM ROOT (Heuchera glabra).—This is an exceedingly pretty plant for placing among cut flowers, its form being quite unique and productive of lightness and elegance, requisites in all floral arrangements.—E. JENKINS.

ROSE ANNA OLLIVIER.—Lovely Rose for the table; good in colour out of doors; indoors, by artificial light, far more beautiful; fine salmon-pink. Its pretty, urn-like form is very distinct. It is best arranged by itself.

POPPY DANEBROG (pink form).—The pink form of Papaver Danebrog, which I send you, appears to be a hybrid between the scarlet and white Danebrog and the pure white Flag of Truce varieties.—C. M. OWEN.

WALL HARRELL (Campanula Portenschlagiana).—Amongst all the pretty dwarf Campanulas I do not think any kind is so satisfactory as C. Portenschlagiana (C. muralis). We find it the easiest to grow and the longest to flower on the rockwork.—C. M. OWEN.

DELPHINIUM TRISTE.—This curious plant is easily grown, and forms a very striking contrast in colour to other flowers at this season. Some of the plants produce very dark brown flowers, but the prevailing colour is sepia to black.—J. W. ODELL, *Burrow Point, Pinner.*

PEONIES FROM IRELAND.—I send you a few Peony flowers. The plants grow about 4 feet high, and the flowers are very fragrant; but, owing to the heat and long-continued drought, the latter are smaller and of less substance than usual.—F. BEDFORD.

PEACOCK POPPY (Papaver pavoninum).—I enclose a few blooms of this new Poppy. It is very free, and will become as popular as P. umbrosum. The flowers droop very quickly, but this is due partly, I believe, to the excessive hot sun we have been having the last few days.—J. W. ODELL.

SCOTCH ROSES.—I herewith send you a gathering of Scotch Roses for your table.—M. WILLIAM, *Kirkcunell, Dumfries.*

*** Among these graceful little Roses, which

deserve a place in every garden, we notice that the colour is far brighter than in many Tea Roses reported to be yellow.—ED.

THE MOCASSIN FLOWER (Cypripedium spectabile).—I send you blooms of Cypripedium spectabile, taken from a nice clump with eighty-nine flowers. It has been planted three years.—F. BEDFORD, *Stratton, Kildare.*

*** A very vigorous and well-flowered spike of this popular hardy Orchid. Lasts well when cut.—ED.

HARDY BULBS IN LONDON GARDEN.—I send a few more flowers. The Liliastrum does very well with me, as you see, as does the smaller form, and the graceful, tall Ornithogalum, which I received as O. Elwesi (but which I am told it is not), is very ornamental. The Asphodelus I send is rather past its bloom; it was very handsome when fully out. The Cyclobothras do very well; the white form is, I think, one of our prettiest bulbs, particularly when grown in a good clump. I ought to have said last week (as you may have some readers who do not know the plant) that the lovely salmon pink colour of the Eremurus and its delightful fragrance are charms added to its stately magnificence.—H. STUART-WORTLEY (Colonel), *Roslyn House, London.*

THE VINE-LEAVED INDIAN MALLOW (Abutilon vitifolium).—I enclose the first flowers we have had here of Abutilon vitifolium. The shrub, now about 9 feet high, was raised from seed four or five years ago, from a plant growing near Bray, county Wicklow, and it was so pretty when I saw it, some years ago, that it is worth risking many failures for one success in growing it. Of two plants shaded from the east by shrubs, only the one completely shaded from the winter morning sun has survived—one of the numerous proofs gardeners have of how small a difference in position may cause success or failure in experiments with plants of doubtful hardiness. A plant from the same batch of seedlings has lived out-of-doors for several winters, against a wall in the Edinburgh Botanic Gardens. Perhaps drought affects this shrub as much as cold does, as I found it drooping greatly to-day from want of water.—C. M. OWEN, *Knockmullen, Gorey.*

NOTES OF THE WEEK.

The Yellow Indian Rock Cress (Tropaeolum polyphyllum).—I send you two sprays of Tropaeolum polyphyllum, which is fast becoming a pest with us.—F. BEDFORD.

*** A beautiful wreath of bloom fully 4 feet long. This plant is very showy when planted on a warm, sunny rockwork where it can ramble at will and display its lovely wreaths of golden orange flowers.—ED.

Allium giganteum.—In THE GARDEN of June 25 (p. 571) "Delta" says that he received an Allium giganteum from our establishment, but that he does not see it in the catalogues, nor in Nicholson's "Dictionary of Gardening." We offered this Allium in our last year's Dutch and Cape Bulb Catalogue, and offer it again in New and Rare Bulb and Plant List, pp. 1-3, and on p. 70 in this year's issue.—ANT. ROOZEN AND SON, *Oeverveen, Haarlem, Holland.*

The weather in Ireland.—The heat and drought are an exceptional experience in this usually damp climate. I fear the garden will not recover the whole summer, as it has become so burnt up. Even the Grass is quite brown, and so many plants must be watered, that those which can get on at all without this attention have to be left to themselves. The drought is becoming very serious for farming as well as for gardening in this part of the country, and after the very dry spring there is much fear of wells, &c., failing if rain does not soon come.—C. M. OWEN, *Knockmullen, Gorey.*

FLOWER GARDEN.

THE ROSY PRIMROSE.

(PRIMULA ROSEA.)

OF the many pretty Primroses that have come to us of late years from the alpine regions of India, none surpasses this little gem in charming beauty. From the time when the flower-buds show the first spot of vivid crimson colour, on stalks scarcely rising from the rosette of yet undeveloped leaves, till the complete expansion of the neat trusses of full pink flowers at 6 inches or 8 inches high, the plant is full of charm and interest. There is a large garden variety considered by some as an improvement on the type, but though it gains in size and strength of colour, it loses in grace and refinement. It is a plant that wants no improving. It is a rapid grower, soon making thick tufts of many crowns. They should be divided at mid-summer by cutting off the whole thick mass of root within an inch of the base of the crowns,

a patch of these growing in a neighbour's garden two years since. He kindly gave me leave to mark a few of the best flowers. I sowed the seed as soon as ripe, and now have numerous plants, some 11 inches over, and carrying great quantities of flowers. I am sure ladies would be delighted with these single Pinks as cut flowers for house decoration.—A. D.

RANUNCULUS LYALLI.

IT is interesting to know from "G. J." that this lovely New Zealand species is to be seen in flower at Reading, and that permission has been kindly granted to see it at Park House, but hundreds of readers like myself cannot spare time to take a long journey for this purpose. If "G. J." would kindly say under what conditions the plant has been grown, whether it is in a greenhouse or planted out of doors, the information would be most valuable. I must say it is tantalising to read an account of a choice new plant, such as that furnished by "G. J.," and to find not a hint of how or under what conditions it has been grown. I have a plant of it in our cool Orchid house, and it is growing remarkably well.

The Rosy Primrose (*Primula rosea*). Engraved for THE GARDEN from a photograph.

when these should be divided singly and planted out in a cool place, where they may either remain, or be replanted in autumn. J.

Single Pinks.—How very pretty are the single forms of *Dianthus plumarius*, the old garden Pink! Those who have not seen these, and, I fear, they are numerous, have little notion of the remarkable beauty found in these medium-sized, but elegantly lacinated flowers. Even the best forms of *D. Heddwigi* are not so finely cut round the edges as these single Pinks are, and the flowers are borne in marvellous profusion on tall stems, so that they are specially useful for bunching. White ground hues predominate, but some are pink and others red; whilst all have carmine, red, maroon, or crimson bands round the eyes, giving them a most distinctive appearance. These single Pinks are also very deliciously perfumed, and that is far more than can be said of many of the flowers which fashion favours. If raised from seed, sown out in the open ground in the month of April, strong plants result for blooming the following year, and, if needed, will endure for years afterwards. I saw

it planted in a pot, but has not yet flowered. I find it is very liable to be attacked by green fly. Our plant is potted in turfy loam, with a little manure and leaf-mould added. This beautiful plant is said to cover the ground for hundreds of acres with sheets of its pure white flowers. It is confined to Middle Island, New Zealand, and grows on mountain slopes at from 1000 feet to 1000 feet elevation. An excellent coloured illustration is given of it in the *Botanical Magazine*, tab. 6888, but no cultural memoranda is given, except that it is stated "the seeds, from one of which the plant figured was raised, were procured per Major Leschke-maker, of Sydenham; they were sown in a tropical heat at Kew in October, 1882, and germinated in November of the following year." The plant flowered in April, 1886. The late Mr. Isaac Anderson-Henry is said to have flowered it previous to 1864, and remarked that the seeds lay dormant for four or five years. "It is known in New Zealand as the Lily, Water Lily, Mountain Lily, and Rookwood Lily." It is altogether a most interesting plant, and anyone who has succeeded in growing it well would confer a great favour by saying how it has been done. The plant must be hardy enough; the ground where it is

found growing is kept moist during the summer by the trickling down of the water from the melting snow. J. DOUGLAS.

Dianthus Greivei.—There is a fine tuft of this Pink on the rockery at Kew, and it may be considered a valuable acquisition. It will probably become a popular garden variety, as it is of the right character to please the amateur. It is the result of a cross between the alpine Pink (*D. alpinus*) and the Sweet William (*D. barbatus*). Its parentage is plainly seen, the individual flowers resembling those of the former, while they are produced in the dense cymes characteristic of the last-mentioned. The colour varies somewhat, being, however, usually bright rosy pink, though occasionally approaching to white. It both grows and blooms freely, and makes an effective rock or border plant.—E. C.

Lathyrus Drummondii.—I have a plant of this that is about 5 feet in height and some 4 feet through. It was a strong plant put out in good soil two or three years ago, and having been liberally mulched in spring it has attained to a large size, and is now covered with trusses of brilliant carmine-red flowers. All that I have done in the way of training is to put a few strong stakes round the plants, and then by winding twine round them, the shoots, which are very numerous, are kept in a compact mass. It is a very striking subject for isolated positions, or it can be allowed to trail over any suitable place. I think it does best when the roots can be kept cool and moist, and if planted in a hot and exposed position, should be well looked after in the matter of watering and mulching.—R. D.

Thrift edgings.—It is not often a Thrift edging forms a feature of the hardy garden, though there are few plants better suited for taking the place of Grass edgings than our common seashore *Armeria*. It would not be wise to advocate the entire use of the Thrift for the purpose, but it might be more often employed under certain conditions than is at present the case. At Kew there is a wide band of *Armeria*, which finishes off a bulb border, and as this is almost destitute of colour at the present time, the mass of rosy Thrift flowers helps to atone for the deficiency. In forming a verge of this description, it is necessary in the first place to well prepare the ground, and, secondly, to plant moderate sized pieces. These with proper care and attention will grow freely, and in the second season after planting will give a good display of flowers. When the weather is hot and dry it is wise policy to water freely, so as to keep the verge as fresh and healthy as possible.—E. C.

New early-flowering Clematis.—When looking through Mr. Charles Noble's nursery at Sunningdale a few days ago, I was much struck with some new Clematises of the patens section raised at the nursery and in course of distribution. They were George Elliot, blue-violet, large, well-formed, eight-petalled flowers of a charming hue of colour, and exquisitely scented, like Violets. We do not appear to possess many fragrant Clematises, but this is one of them. Then there is Lady Constance Kennedy, a charming pure white variety. On young plants the flowers are single, but as the plants increase in size they become semi-double and double, and it is very free indeed. This makes an excellent addition to our pure white early-flowering Clematises. Lord Beaconsfield has light lavender-grey flowers of good form and large size. Mr. Gladstone is of a light azure blue-grey, a very pretty shade, large in size, and of fine form. The last is Daniel Deronda, mauve-violet, flushed with red, and with a slight flame of white on each petal. This variety sometimes comes semi-double. These Clematises are propagated very largely and with great rapidity. They are worked—*i.e.*, grafted—on roots of *Clematis Vitalba*. Grafting is done about the middle of March, and the graft is tied round with a bit of raffia, which rots, and therefore saves the trouble of cutting away. They are then plunged in bottom heat in frames within a propagating house, and as soon as they have made a shoot of 6 inches or 8 inches in length, they are placed in a cooler temperature, then shifted into 4½-inch pots as they

require it; and when sufficiently hardened off, they are plunged in beds in the open ground for sale in autumn. The wood made during the summer ripens off and produces flowers in May and June following; therefore, it must not on any account be cut away, as in the case of *C. Jackmanni* and others of that type. Some of these early-flowering Clematises, if planted out among varieties of the *C. Jackmanni* type, that bloom through the summer and autumn, by reason of their flowering some time before the latter, give a desirable succession of bloom throughout the summer.—R. D.

NOTES FROM EDGE HALL.

ACHILLEA MONGOLICA.—A giant relation of *A. ptarmica*, very free flowering. I am unable to verify the name, having no description of the species at hand.

* * One of the prettiest composite flowers we have ever seen, very bright and distinct in its effect.—ED.

CHRYSOGONUM VIRGINIANUM (A. Gray).—A distinct and long-flowering plant of a new character.

* * Quite distinct. Very rich colour.—ED.

HEMEROCALLIS MIDDENDORFIANA.—A bright, large form of *H. Sieboldi*. The plant came to me from W. Thompson, of Ipswich (who generally takes the lead with novelties of merit) ten years ago. I see it has at last been exhibited before the floral committee at South Kensington.

VERONICA TEUGRIUM FLORE-ALBO.—A white-flowered form of the rock plant, generally sold as *V. rupestris*. I never saw it in my garden before, though my gardener says I sent it from the Pyrenees last year.

PENTSTEMON GLABER.—A prostrate plant with brilliant blue flowers, from W. Thompson's seed.

ANEMONE NARCISSIFLORA.—This grows 2 feet high in my garden, bearing a dozen bunches of flowers, bright pink, in bud like an Apple flower, and not unlike it when open.

HIERACIUM VILLOSUM (Lin.).—This is an excellent plant in bright sun, never flagging with heat or drought. It is a long-lived perennial easily raised from seed. I raised it from seed sent by W. Thompson. The *Hieraciums* are not very easy to identify, and I should not wonder if this is the *H. valde-pilosum* of Villars (Flor. de Dauphiné) offered in Baekhouse's catalogue. It is very ornamental and bright.—C. WOLLEY DOD.

* * A very distinct and pretty plant, the effect quite curious from the contrast of the downy buds and the soft yellow flowers.—ED.

P.S.—Since writing the above I hear from Mr. W. Thompson that he carefully verified the name of the Hawkweed, *H. villosum*. He is seldom wrong in his names, and so I think this name may be trusted.

Canterbury Bells.—The variation in colour which is now to be found in a good strain of Canterbury Bells is remarkable, and generally the diverse tints show such close assimilation to those nearest them that distinct division into colours seems impossible. From pure white down to deep purplish blue there is room for pink, mauve, peach, heliotrope, lilac, and many diverse shades, all of which may be found in plenty. A large bed of some four rods of ground in extent is just now indeed a fine sight; the plants being strong, and, as all are erect and in full bloom, they are distinct and effective. The single forms open first, and after these come the semi-doubles, that is, those having two cups, one just within the other; latest of all come the most double kinds, the cups being crowded into the outer one so thickly that the flowers are very solid. The semi-double forms usually are the finest and have the most graceful outline. These are not to be confounded with the quaint, showy Calycanthema, or Cup-and-saucer forms, which also have several distinctive and some closely allied hues; indeed, the Canterbury Bell is so sportive, that it seems useless to attempt to fix colours, and I do not see that it is desirable, as the greater variety the more pleasing the result.

The seed as a rule germinates badly in the open here, because the ground is hard in texture; but in good, soft garden soils it may be sown freely, and no better time than early in the month of May with other biennials. The plants should be got out early, as the sooner they are planted the finer will be the pyramids of flowers the following year. The earlier blooms at the top of the spikes have short stems, but lower down the stems are very useful for cutting.—A. D.

PYRETHRUMS.

THAT the Pyrethrums, double and single, make excellent border plants, and are most useful for cutting purposes, no one will deny. In May last I was in a west of England nursery, where there was a large bed of Pyrethrums, and found many of the plants had been lifted, put into pots, and placed in a cold house, where they came on into flower earlier than those in the open ground. As the soil was well moistened before the plants were lifted from the open, there was no check experienced, and it was said that the flowers obtained a few days earlier came in very useful at a season of the year when they are somewhat scarce.

At the meeting of the Royal Horticultural Society, on the 14th ult., and of the Royal Botanic Society, on the 15th ult., the Pyrethrums could be seen in all their glory, and in great variety. It is within the past forty years that the double Pyrethrum has developed from the single into the large, full, double form, as seen in the present day. But the single varieties are not overlooked, for they could also be seen in great variety and striking colours. If the late Mr. John Salter—to whom we owe the double varieties—could see the rich coloured single flowers developed since his death, he would probably own they were well worthy of cultivation, especially those having deep crimson shades contrasting so well with the yellow disc in the centre.

Messrs. Kelway & Son, of Langport, are now our foremost raisers of double Pyrethrums. They have produced very fine and striking forms in Melton, bright crimson-scarlet; Ormonde, rich rosy red; Figaro, carmine-rose, very bright and fine; Empress Queen, delicate blush, very pretty; Florentine, the most delicate of all the blush varieties, large and full; Duchess of Teck, pale rose, very pretty; Magician, clear pale pinkish rose, a charming variety, having an orange centre; Gazelle, pale rosy pink, very pretty; Mega, flesh with orange centre, very pretty; and Pericles, pale primrose ground tinted with delicate rosy pink. These are all new varieties raised by the Messrs. Kelway & Son, and represent the latest improvements in the flower.

Of older varieties, the very finest are Brilliant, rich rosy purple; Captain Nares, bright crimson; Coquetterie Flore, purplish lilac, very pretty; Gloire d'Italie, rosy red, very fine; Hobart Pasha, maroon-crimson, very fine; Madame Munier, rosy lilac; Mons. Barel, purplish crimson; Ne Plus Ultra, blush white; Placida, peach, very fine; Princess Metternich, pure white with slight rosy ring in the centre; Rembrandt, rosy purple, extra fine; Rose Perfection, lilac, very pretty; and Wilhelm Krumper, rosy lilac, very fine. Here, then, is a collection varied, numerous enough, and comprising the best flowers yet raised.

New single varieties appear to be numerous produced. Of those raised by Messrs. Kelway and Son, and shown on the above dates, special mention should be made of Merry Hampton, brilliant crimson, very fine; Rêve d'Or, brilliant scarlet-magenta; Sulphur Queen, delicate sulphur; Oliver Twist, pale blush with thread-like petals; Lucifer, dark crimson; Abianus, white; Abrupolis, pink, very fine and pleasing; Arnold, amaranth; Cabades, white; Escalus, bright purple, very fine; Fundanus, flesh white; Glowworm, purple-crimson, very fine; Tarsius, flesh colour; and Zelia, rosy lilac.

A few good older varieties will be found in the following list: *Astræa*, rose, very fine; *Bellona*, pink and white; *Hebe*, white; *Plutus*, carmine-rose, very fine; *Saturn*, purplish red; *Sylvanus*, maroon; and *Venus*, flesh-coloured.

The propagation of double and single Pyrethrums is a simple matter. Those who have a few large plants of good varieties can easily increase them by dividing them in the autumn when they have done blooming. Any side shoots that may not have put forth roots make very good cuttings if taken off in autumn also, and pricked out in a prepared bed made up in a cool frame or if placed in pots. If carefully looked after, by spring the cuttings should have made rooted plants fit for planting out in a prepared bed.

The double Pyrethrums do not seed freely in this country, but seeds can be had saved in France and Germany, and, as far as our experience has gone, good varieties can be raised from it. If sown in early spring in pans of fine light soil, the pans placed in a cold frame and covered with a hand-glass, the seeds will germinate. The young plants need to be shaded from the sun and encouraged to grow on into size for planting out to flower.

Slugs are troublesome to Pyrethrums, as they devour the young growths. Some rough sand sprinkled on the soil about the plants will help to keep them away, and they should be picked off by the hand also. R. D.

NOTES ON HARDY PLANTS.

Aster alpinus var. rubra is likely to prove an acceptable dwarf Daisy for early summer effect in the rock garden, and it is a charming companion to the blue and white kinds. About the beginning of June we have none too many composites, and no more desirable flowers could be employed in groups. The habit of all the varieties of *A. alpinus* is very neat, and the heads are freely produced. The var. *rubra* might be more strictly described as pinkish than red. Like the others, it will grow better if propagated annually from cuttings, and the plants in their second year produce the best effect.

Primula purpurea (Royle).—A splendid scape of blossom was most carefully tended in a well-aired cold frame, with a view to the saving of seed. The capsules were well formed and large, and kept fresh for a long time, but when they began to wither and were examined, not a seed was to be found.

P. Reidi, so quaint, distinct, and also so beautiful, seems now to be maturing seeds, and on examining the seed-pods, one is struck by the beauty of the calices, which are campanulate in form, large, broad, and plainly toothed; all the inner surfaces are thickly coated with a creamy white meal which may be seen round the toothed edges. Many flowers are less showy than these large bell-shaped and pendent calices, which are, moreover, of an enduring nature, and retain the delightful perfume of the younger flower. It is to be hoped that so distinct a Primrose will be quite hardy in England.

P. reticulata.—From various sources I had seed, supposed to be of this desirable Himalayan Primrose. All, however, so far prove to be but slightly varying forms of *P. sikkimensis*, which, well marked as they are, come far short of the description belonging to *reticulata*. Among plants sent me by Mr. Dod, there are many fine, dark yellow-flowered forms, and the almost chestnut-brown calices are an additional feature. In the foliage, too, there is great dissimilarity. So far as I have observed, a fine batch of seedlings raised under the name of *P. Kingi* is more likely to yield the desirable *P. reticulata*, but, as yet, all seems to be uncertainty. Anyone raising seeds of the Himalayan Primroses is likely to be struck with their character as regards the variety of sorts they produce.

P. bellidifolia in my hands has been another proof of the statement just made. From Dr. Appleton and Mr. Wolley Dod seeds came as *P. capitata*, but from Mr. Dod the words "or *bellidifolia*" were added. From the latter's, however, there proved to be far fewer plants of *bellidifolia* than from the seed sent by the former. The plant from the time it gets its second pair of leaves is quite distinct from *P. capitata*, and if I relate what occurred, the reader may judge whether the description of the leafage of these seedlings is correct.

Messrs. Gumbleton and Poü called here last November and asked about a few plants they saw in a box. I promised a plant to Mr. Gumbleton on his reaching home. Before sending, he wrote asking me if I was quite sure the small plants he saw were not weeds of the common Daisy. I think the plant pretty well justified his suspicion, and I am sure the untidy and weedy state of things he saw might easily enough lead him to suppose Daisies could be flourishing among Primroses, but as it happens he was wrong, as I hope his plant may have shown, and as my plants have shown. The flattened rosettes of smooth and all but meallless leaves are totally distinct from those of *P. capitata*; the scapes are shorter and stouter in proportion, and the heads of blossom totally different both as regards colour and arrangement; of course this may well be expected, for though the seedlings came up among *P. capitata*, the seed may have been taken from different plants. We are less disposed to put the two types far asunder when it can be shown, as I believe I shall be able to show, that by slow gradations they are linked together. I have not flowered more than four or six plants, and they have been the more typical specimens; those yet to flower approach *P. capitata* by such features as a little farina, wrinkled and serrated leaves, and otherwise by various deviations, but in all there prevails the distinct habit of flattened or spreading leaves—even the youngest central ones—and the midrib is broad, succulent, and irregular. The appearance of the plant after flowering is not such as to lead one to suppose that it will prove biennial, like *P. capitata*, for it makes compact crowns more like *P. rosea*; it also produces seed freely.

Polygonum capitatum reproduces itself freely from self-sown seed. The seedlings make rapid progress, and flower the first year under favourable conditions. It is worth while, perhaps, to pot a few of the later plants for keeping during winter in a cold frame, where, when kept dry, they will stand much frost. Treated in this way, the plants begin to flower soon after they are planted out in spring, and keep on blooming all the summer. J. WOOD.

Kirkstall.

Golden Drop (*Onosma taurica*).—Many grow this interesting plant, but it is seldom we find it displaying its true character by reason of improper treatment. It is neither fastidious nor tender, and flourishes best in a gravelly soil, or one in which Cactases delight in, bearing full exposure to the sun with impunity. It is advisable to slightly shelter in winter, and during hot weather to water freely; when treated in this manner the leafage is remarkably robust, and the golden yellow pendent flowers are produced with great freedom. These last well in water, and, owing to their elegance and refined appearance, may be utilised for table decoration. It strikes readily from cuttings.—E. C.

Phacelia campanularia.—This is a glorious blue-flowered plant, sadly wanting an English name. I should like to term it Blue Cup, for the lovely flowers are cup-shaped and erect. The plants from an early sowing came thinly, sown, I fear, too early—indeed, before the March snowfall, but those spared are now blooming beautifully. In colour the flowers rival the Gentian, but have more gloss. The plants flower almost close to the ground, sending out several stems which bloom for several weeks. It is probably the most effective of blue-flowered hardy annuals we have. A later sowing made in April has given plants in abundance.—A. D.

Pink Dog Violets.—"R. L. A.," on page 591, asks whether a variety of *Viola canina* with pale pink or mauve flowers is rare. It grows in great abundance in a garden near Ryde, from which I have introduced it to my garden. In the garden referred to it comes true to colour from seed, not being mixed with other Dog Violets. I have never seen this colour in wild Dog Violets, though I have sometimes found pure white. The Dog Violet is capable of being made in gardens an ornamental spring flower by judicious treatment. I have seen it growing wild in the lake district on heaps of limestone *débris* with such dense masses of flower

and of so bright a colour, that I could scarcely believe its identity. I have also seen it very ornamental on old walls, but on strong or rich soils it becomes rambling and untidy. Such a blue as that of the typical Dog Violet is always welcome in a spring garden, and by timely sowing the plant may be made neat and elegant.—C. WOLLEY DOD, *Edge Hall, Malpas*.

HIMALAYAN PRIMULAS.

I WAS glad to see Mr. Douglas' letter about these plants in THE GARDEN (p. 552), as I had seen no previous account of the results of the large collection of seeds made by Dr. King's collectors in 1875, and which were so liberally distributed through the Horticultural Society last spring. It is not surprising that many of the names have turned out to be incorrect, as all, or nearly all, of these seeds were gathered by natives in parts of Sikkim which are inaccessible to Europeans on account of political and other difficulties; and though some of these natives know the plants of their country remarkably well, yet, as the seeds must be collected when the flowers are no longer visible, and the dried plants which they are instructed to bring with them often get mixed, confusion occurs among the names. But we must be very grateful both to Dr. King and to Mr. Gammie for the trouble and expense which they take to introduce these plants, and hope that in a few years it may be possible for Europeans to visit more of these rich and interesting localities.

I will make a few remarks about the Himalayan Primulas, hoping to induce Messrs. Llewellyn, Dewar, and Sinclair to give us some notes on the culture of the numerous species which are, or have been, so well grown at Kew, Edinburgh, and elsewhere. I take them in the order of the "Flora of British India," which is the latest and best account of them I know:—

P. ROTUNDIFOLIA (Wall.).—Kashmir to Sikkim; 11,000 feet to 13,000 feet. I raised this in 1882, but soon lost it. Is it now in cultivation? I think not.

P. GAMBELIANA (Watt.).—Jongri (a yak pasturage about nine marches north of Darjeeling), 14,000 feet; not introduced.

P. PULCHRA (Watt.).—Jongri and Lachen, 12,000 feet to 14,000 feet. A small, but very handsome plant, which I think has never introduced alive, but which might be procured, as Jongri is accessible.

P. RETICULATA (Wall.).—Sikkim, 10,000 feet to 15,000 feet. This plant, which I found in the interior, is described as very like *P. sikkimensis*, and as Mr. Douglas says the seedlings vary much, it is quite possible that his living specimens would break down the supposed distinctions. They should be compared at Kew. I should be glad to have a few plants of this for comparison.

P. VAGINATA (Watt.).—Sikkim; only found by Mr. Clarke; not introduced.

P. CLARKEI (Watt.).—Kashmir, 7000 feet. Habit of a *Viola*; not introduced.

P. MOLLI (Hook.).—Bhotan. A robust plant, but not hardy, which has lived for many years and seeded annually in my greenhouse.

P. GERANIIFOLIA (Hook.).—Chumbi valley (between Sikkim and Tibet); 10,000 feet. This I have never seen, and hope Mr. Douglas will spare me a plant to be figured in the Bot. Mag.

P. FILIPES (Watt.).—Bhotan, 6500 feet. Allied to *P. obovata*, but smaller; not introduced.

P. LISTERI (King).—Tonglo, near Darjeeling; 9000 feet to 10,000 feet. Perhaps the same as the last. I searched for it last year in the dense Bamboo thickets where it grows, but without success.

P. DENTICULATA (Smith).—Kashmir to Bhotan and Khasia; 5000 ft. to 13,000 ft. The numerous varieties in cultivation which go under the names of *cashmeriana*, *purpurea*, &c., all belong to this very wide-ranging and variable species.

P. CAPITATA (Hook.).—Sir J. Hooker is inclined to keep this as a form of *denticulata*, but its annual or biennial habit and general appearance seem to make it for garden purposes a very distinct plant. Has anyone found it to be truly perennial like *denticulata*?

P. EROSA (Wall.).—Kumaon to Bhotan, 1500 feet to 9500 feet; but not known in Sikkim. A good perennial species, but not hardy with me.

P. BELLIDIFOLIA (King).—Sikkim, 13,000 feet. Has anyone raised this from Dr. King's seeds?

P. FARINOSA (L.).—Hardly a Himalayan plant, though found in Ladak, Central Asia, and Europe.

P. HEYDEI (Watt.).—Also a Ladak plant; 12,000 feet to 14,000 feet. Not introduced.

P. CONCINNA (Watt.).—Sikkim, 15,000 feet to 17,000 feet. A minute plant in the way of *farinosa*, but botanically distinct.

P. GLABRA (Klatt.).—Sikkim, 13,000 ft. to 15,000 ft. A small, distinct species; not introduced.

P. SIBIRICA (Jacq.).—A wide-ranging species, found in the high, dry regions of the N.W. Himalaya.

P. INVOLUCRATA (Wall.)—MUNROE (Lindl.).—A hardy perennial with me.

P. TIBETICA (Watt.).—West and East Tibet; 15,000 feet to 17,000 feet. Near *sibirica*.

P. ELLIPTICA (Royle).—N.W. Himalayas and Ladak; 8000 feet to 12,000 feet. This is a distinct and beautiful plant which ought to be in cultivation, but I have not seen or heard of it. All the species which come from the drier regions of the north-west are more easily grown than those from the wetter mountains of Sikkim.

P. ROSEA (Royle).—N.W. Himalayas at 10,000 feet to 12,000 feet. This and *sikkimensis* are, in my opinion, the best and easiest grown and increased of all the Himalayan species, but both should be treated as biennials to have them in perfection.

P. PROLIFERA (Wall.) = *IMPERIALIS* (Jungb.).—Chumbi, 11,000 feet; Khasia, 6000 feet; Java, 10,000 feet. A fine plant, which is now in cultivation from the produce of a single plant raised by the late Mr. A. Henry, from seeds which I procured from Sikkim several years ago. It has now been raised by Mr. Douglas and others, and as it has proved difficult to grow, I will state the conditions under which I saw it in the Khasia hills last September. It probably requires some protection from frost in winter, but flowers early, before the heavy rains commence, and grows in a wet, black, marshy soil. After flowering, it requires much moisture and becomes almost an aquatic, ripening its seeds early in September when the plant is at times under water. Its long, strong roots penetrate deeply into the mud among Reeds and coarse Grasses.

P. OBTUSIFOLIA (Royle), Himalayas 10,000 feet to 12,000 feet; *P. ELONGATA* (Watt.), Lemu Valley, Sikkim, 12,000 feet to 13,000 feet.—Perhaps only forms of one species. A form of *obtusifolia*, called *Gammiana*, was raised by Mr. Douglas and shown this year.

P. STUARTI (Wall.).—Himalayas and Tibet, 12,000 feet to 16,000 feet. There are many varieties of this wide-ranging species, of which perhaps the best is *P. purpurea* (Royle), not the *purpurea* of gardens, which is only a form of *denticulata*. This seems to be in cultivation under the name of *Jalschikiana* (Kerner), but I have not seen it. The typical yellow *P. Stuarti* (Bot. Mag., 4356) is not unlike *P. luteola* in appearance, and does not seem an easy plant to keep.

P. SIKKIMENSIS (Hook.).—Sikkim, 11,000 feet to 15,000 feet. This lovely sweet-scented species is very easy to cultivate, but cannot bear sun or drought. It comes up so late, that it is never injured by spring frosts, and does well in pots as a semi-aquatic. My stock, however, all died in the open ground from drought during my absence last summer, and I shall be glad of some fresh plants of it.

P. KINGI (Watt.), *P. ELWESIANA* (King).—Both of these fine and distinct plants grow at about 12,000 feet at Natong, on the road from Darjeeling to Tibet, and flower in July in wet, marshy places. I was in sight of this spot last August and hoped to procure fresh seed, but the road being occupied by a Tibetan force, who have practically invaded British territory and remain in defiance of the mild remonstrances of the Indian Government, I was unable to proceed. I hope, however, to procure seed this year. If anyone has raised either of them I should be glad to know of it.

P. DICKIEANA (Watt.).—Sikkim, in the Lachen Valley, 10,000 feet to 13,000 feet. A beautiful plant, like a small *Stuarti*, and, according to Sir Joseph Hooker, who alone has seen it in flower, scentless.

P. TENELLA (King), *P. PUSILLA* (Wall.), *P. SAPHIRINI* (Hook.), *P. UNIFLORA* (Klatt.), *P. SOLDANELLOIDES* (Watt.).—All these are minute species, growing at great elevations, 12,000 feet to 16,000 feet in Sikkim, and not likely ever to become good garden plants

on account of their small size and difficult cultivation. The only one I have seen in cultivation is saphirini, which I had for a year or two; a pretty little thing, but I soon lost it.

P. PETIOLARIS (Wall.).—*Sinla* to Bhotan, 4000 feet to 12,000 feet. This is a very fine species, very early-flowering. I have seen it on the Nepal frontier in Sikkim, at 10,000 feet, in great beauty in March. I gathered ripe seeds last year in July on Tonglo, and sent them to M. Leichtlin, who has raised it. It is a plant that should be kept in a damp and shady spot, and will probably require some protection in winter. There are many varieties of it.

P. MINUTISSIMA (Jacquem.), **P. REPTANS** (Hook.), **P. MUSCOIDES** (Hook.), **P. HOOKERI** (Watt.), **P. STIRTONIANA** (Watt.).—These, again, are all little-known species found at great elevations, and none of them from the descriptions seem to be of any great horticultural value.

P. FLORIBUNDA (Wall.).—A low-level plant (2500 feet to 6500 feet) of the N.W. Himalayas, allied to *P. verticillata*, a greenhouse plant with small flowers, but I have not seen enough of it to say whether it is worthy of general cultivation.

P. REIDI (Duthie).—A newly-discovered species (from Kumaon?) which I saw in flower this spring in London. It is distinct, but does not appear to have much horticultural merit.

Out of these forty-four species we have about eighteen only in cultivation of which I should say *P. denticulata*, *capitata*, *erosa*, *rosea*, *prolifera*, *Stuarti*, *sikkimensis*, *petiolaris*, and *invulnerata* were the best. Of those not introduced, the following are worthy of some trouble: *P. pulchra*, *elliptica*, *Kingi*, and *Elwesiana*; while the whole of the remainder will be of high interest from a botanical point of view.

Preston, Cirencester.

H. J. ELWES.

SHORT NOTES.—FLOWER.

Japan Rose (*Rosa rugosa*).—There is a well-developed plant of this in bloom on the rockery at Chiswick. The newly expanded leafage is of a rich green, and the deliciously fragrant flowers are of a delightful rosy crimson colour.—E.

Edelweiss.—This hoary plant may be seen in condition now on the rockery at Kew. It is provided with a moist, sandy, peat soil, which seems to thoroughly agree with its requirements. It is a most interesting alpine herb when well grown.—C.

Balearic Sandwort.—This is invaluable for running over the facings of stones, clothing them with a green carpet. At the present time it is smothered with small, pure white, star-like flowers, which give it a distinct and inviting appearance. *Arenaria montana* is of the same character, but its flowers are four or five times as large.—E.

Bellflowers in pans.—These lovely plants are not often seen in pans, but in this way they may be grown with advantage. My method is to grow the dwarf Bellflower (*Campanula pumila*) and the Austrian Harebell (*C. pulka*) in small pots, and when in flower to remove them to shallow pans, arranging them so as to obtain a pleasing harmony of colour. The snow-white flowers of the former and the deep violet-purple of the last mentioned make a fine contrast.—E.

Cabe Pondweed (*Aponogeton distachyon*).—This is now blooming freely, and its white fragrant flowers are welcome. There are few beautiful water plants of such hardy constitution as this, and it is useful both for a greenhouse tank and ornamental pond. It succeeds best in running streams, and on some of the Portuguese rivers, where it has been introduced, it has become a noxious weed.—E.

White Fraxinella (*Dietum fraxinella alba*).—This is flowering freely in the herbaceous border at Chiswick; its spikes of pure white flowers are very pretty. It is at once distinct and handsome, and a charming companion for the type.—E.

Wall Bellflower (*Campanula muralis*).—This is a charming Bellflower for clothing the stonework of the rockery, which it covers with a dense mat of vegetation. It is at the present time a mass of pale violet flowers. We have often seen it in splendid condition in cottage windows.—E.

Eremurus Korolkowi.—This is a very rare species, or rather variety, of *E. Aucherianus*. The flowers are rose or whitish, but I fear Mr. Tallack's plant is not true to name. It grows in very remote quarters, and I fancy it is not yet under cultivation. It stands next to *E. robustus*, and is a very showy plant.—MAX LEICHTLIN, *Baden-Baden*.

Ivy and Clematis Jackmanni.—These harmonise effectively, the dark leafage of the former bringing out conspicuously the rich purple-coloured

flowers of the Clematis. In growing them together, the plants of the latter must be closely attended to, so as to prevent the more vigorous Ivy smothering them. We could by a little forethought obtain rich effects in the garden, as in this case.—T. W.

TUFTED PANSIES.

THERE has, unfortunately, been a falling off in the number of cultivators of these handsome flowers within the last few years, which is much to be regretted, seeing what a charming sight a good selection presents when in flower. The reason of this falling off in the number of growers is not far to seek, for no experienced person would question the statement that they are rather difficult subjects to deal with. This feature in their behaviour may be overcome by pursuing a judicious system of management in the late summer and autumn months. I find that the southern growers treat them too tenderly as a rule during the winter, which makes the plants so weak, as spring advances, that they quickly succumb to any unfavourable influences when they are planted. They are certainly not tender in the strict sense of the word, although I should not advise anyone to risk the whole of their stock in the open without affording them some protection during the winter. That they are not tender, I have proof here, where we have some clumps now in fairly good health, that have stood for years without being disturbed. To keep them through the winter in the open ground, I find that the soil must be well drained, as damp is a greater enemy than frost. It is also necessary to stir up the surface lightly round the plants in the autumn, to allow the water to percolate through the soil. I have watched the behaviour of Pansies rather closely for some years, and I am satisfied that the principal cause of the plants dying out is through exhaustion, by the plants being allowed to continue longer in bloom than is good for them; the result of which is, the stock becomes so weak that the cultivator cannot get sufficiently strong growth in the autumn to perpetuate his plants. He must, therefore, do so with weakly cuttings or offsets; the consequence is, the plants do not get sufficient strength to go through the winter without a good deal of coddling, and many losses occur. Besides heat and drought, which cause the plants to die away during the summer, losses occur through the continuous flowering of the plants. This feature is more remarkable in those varieties bearing medium-sized flowers than in the case of the large ones.

In a good soil that is favourable to their growth, Pansies will continue flowering until quite late in the summer, and I need hardly say that, when allowed to do so, the plants are weakened thereby. Every cultivator of Pansies ought to be content if his stock is in flower three months, at the end of which all the flowering shoots should be cut off. Strong, well-hardened plants, put out early in April, will be in flower in a month (except, perhaps, in the north); in any case, three months are long enough to allow them to be in flower, as by that time the strength of the plants will be exhausted, having in view that the cultivator wishes them to live, and by the early autumn to provide him with cuttings in sufficient numbers and strength to perpetuate his stock. Acting on this principle, the plants will be cut over at the latest by the middle of July, which leaves them sufficient time, while the weather is favourable, to make growth to produce fresh shoots from the bottom, and that sufficiently early in the season to admit of them being rooted before winter sets in.

Plants raised from cuttings are undoubtedly the best. They not only grow more compact, but they grow with greater vigour, and produce larger flowers than plants raised from offsets. A place for the cuttings should be prepared on a border facing east or west, where they will be shaded for about half the day. Plenty of sand should be mixed with the soil. The cuttings should then be made about 2 inches long, and dibbled firmly in the earth, and some handlights placed over. They will require a little shading at first, and the soil must be kept constantly moist. At the end of a month a little air may be given them, and the quantity increased

as the growth progresses. The best place in winter for plants raised in this way is in a cold frame, where they can be protected from severe frost and heavy rain. Many increase their stock in the autumn by dividing the old stools. This plan gives much less trouble, as after the plants are pulled to pieces, and the oldest portions rejected, they can be placed at once where they are to remain during the winter, but such plants are not equal to those raised from cuttings.

The treatment of Pansies during the winter need not involve much labour. In mild weather the frames should be ventilated night and day, and on all favourable occasions the lights should be drawn off early in the morning and put on again at night. Slugs are often troublesome during the winter, and the most satisfactory way of destroying them is to search the frames at night with a candle.

With regard to the after management, very few care to devote frames to flower them in, but I can only say that the best blooms I ever saw were grown in frames by an amateur; his flowers were exceptionally large, all the markings clearly defined, and the colours distinct. This grower used to have from three to five plants in 8-inch and 10-inch pots instead of a bed of soil, which enabled him to remove his plants to a cool position as soon as bright weather commenced. Seeing that the majority of cultivators must grow their plants in beds in the open, I recommend them to use as sheltered a position as possible, providing it is not draughty. If the soil is fairly heavy, they are better without strong manure. They like a gritty staple for the roots, therefore a fair proportion of coarse sand should be incorporated with the soil, and in dry weather they will be much benefited by a mulching of Cocoa fibre or decayed Fern.—J. C. C., in *The Field*.

A DAY ON THE SNOWDON RANGE.

WE may safely say that no other county—nor, indeed, any equal extent of ground in Britain—can boast of so rich a flora as Carnarvonshire. At least three plants, *Lloydia serotina*, *Cotoneaster vulgaris*, and *Potamogeton Griffithi*, have been found wild in no other part of the British Isles, while many others are extremely rare, a number having only been recorded from one or two other stations, and there very sparingly distributed. In the following brief notice of a botanical trip, which occupied but a single day, a short description of some of the rarer plants met in with would, we thought, not only be of interest, but serve to show what a rich ground for botanical research are the gorges and tarns of this imposing mountain range, and that even as early as the latter end of June. Ascending from Ogwen Lake, two other friends and myself leisurely crossed the Myddyn-bach, and on peeping into some of the clefts and crevices of the rocks we saw numerous fine sheets of *Hymenophyllum Wilsoni* and *Saxifraga oppositifolia*, the latter just out of flower, but plainly showing, from its numerous partially withered flower-stems, what sheets of purple must have been revealed but a few weeks before. *Saxifraga stellaris* was in all its glory, the quickly sloping banks of half the rivulets as well as sides of the damper, almost dripping, rocks being literally carpeted with its deep green rosettes of foliage and abundance of pinky white starry flowers. The Mountain Saxifrage (*S. nivalis*) we likewise saw in small quantities, usually in some shady, dampish, north-facing crevices, and not unfrequently in company with that pretty, fresh-looking Fern, *Asplenium viride*. Higher still, and away through a deep, rocky defile—glorious botanising ground—we ascended the Myddyn-mawr, and were fortunate enough to spy out, on an almost inaccessible ledge of rock, the pretty creamy white-flowered *Drvas octopetala*. Along with it was growing the Mountain Cudweed (*Antennaria tomentosa*), whose everlasting flowers vary almost as much in depth of colouring as do the stems in the height to which they rise from the proeminent silvery-white foliage.

Here peak after peak of the hazy hills rise behind each other, and one sees at a short distance what, until he has gained their craggy heights, appeared

the highest of all, but when topped, alas! as often before, others more majestic rise up in view and almost make one give up in despair of ever attaining the highest peak.

Whilst quietly seated on the edge of a mighty precipice—another gap of Dunlow—a treat both rich and rare met our gaze, for there at no great distance below the sweet little flowers and lush-like foliage of the Mountain Tulip (*Lloydia serotina*) were distinctly to be seen. There, indeed, they were, but out of reach, one beautiful tuft of a dozen or more and thickly studded with flowers being just 1 foot beyond our grasp—just as well, perhaps, for irresistible temptations come alike to botanists and ordinary plant collectors.

Whilst gazing on these diminutive plants in this their only known British station, we could not help recalling Grant Allen's pleasant, but wisely misleading description in *Louquans* of the plant which he chooses to style as a degenerate and dying out member of the Lily family. Growing not far distant from the latter we were delighted to find the dwarf or Welsh Golden Rod (*Solidago virgaurea* var. *cambrica*) blooming in all its beauty. A lowland clime and the best cultivation do not alter this plant's habit in the least, the low, sturdy nature—flowers and all rarely exceed much over half a foot in height—having been grown for six or seven years in various gardens I know. It is a pretty little alpine that we prize much, the close-set and longish flower-spike being of the brightest yellow. Of the *Thalictrums*, with their ornamental Maiden-hair Fern-like foliage, we saw two forms, the lesser, *T. alpinum*, being particularly abundant on some of the slopes. What a diminutive and withal pretty plant it is, so fragile-like and yet so wiry, for growing on the bare, breezy rocks and at these high elevations must try any plant.

By the sides of the streams *Geum montanum* and *Meconopsis cambrica* were fairly abundant, while drier portions of the same ground were thickly carpeted with the bright green foliage and occasional flowers of *Saxifraga hypnoides*. Along the sunny, bare rocks we noticed but few plants of the Cloudberry (*Rubus Chamæmorus*), but what we saw looked unusually healthy and vigorous.

Many of the rocks were clothed very thickly with the reddish purple flowers of the Moss Campion (*Silene acaulis*), whilst *Anemones*, blue and white, just peeped out from the deep and more shady crevices, but these latter were past their best, only a few late straggling blooms being left. *Erica vulgaris*, *E. cinerea*, and *E. tetralix* were abundant; *Vaccinium Vitis-idaea* less so; while the nearly allied *Empetrum nigrum* clothed the rugged tops of many of the higher peaks. Treading the shores of a little mountain lake on our return journey, we were fortunate in discovering numbers of the rare European Quillwort (*Isoetes lacustris*) and *I. echinospora*, and on the banks of the same, growing amongst Rushes, and *Sphagnum* were a few plants of one of our smallest and rarest of Orchids, the bog *Malaxis* (*M. paludosa*), *Ptilularia globulifera* we also saw, and not far off a quantity of the water *Lobelia*, *L. Dortmanni*, was seen forming vivid green cushions at the lake bottom. Ferns were particularly abundant, amongst the rarer being *Cystopteris fragilis* and *C. dentata*; the Parsley Fern (*Allosorus crispus*), *Lastrea montana*, *Ophioglossum vulgatum*, *Botrychium lunaria*, as well as the already recorded *Hymenophyllum Wilsoni*. Of Orchids, as well as the bog *Malaxis* mentioned above, the sweet little *Habenaria bifolia* and the lesser *H. albida* were abundant on the hilly meadows, and *Orchis conopsea* scented the air for a considerable distance from where they grew. *Listera ovata* and *L. cordata*, the latter reaching the greatest altitudes, were likewise met with, while the true Marsh Orchid (*O. latifolia*) was just coming into flower, and would, in another fortnight, give a glow of purplish pink to the swampy grounds in which they were growing. *Pedicularis sylvatica*, of the purest white, was found in abundance, but only in one particular spot, the normal form being, however, abundant everywhere. Three forms of the Milkwort (*Polygala vulgaris*), pure white, purple, and deep pink flowers, were very often seen on the

downward journey, and in many places rendered the Grass amongst which they creep highly attractive as well as somewhat misleading.

A. D. W.

MANY-FLOWERED WOOD SORREL.

(*OXALIS FLORIBUNDA*.)

THE *Oxalis* genus contains a large number of charming garden plants; indeed, so graceful in habit and so floriferous are they, that the majority would be included even in choice collections. Unfortunately, it is almost impossible to grow the greater part of them out of doors with any degree of success, but they may be easily cultivated in a cool greenhouse, and the rich and varied coloured flowers make a fine display. A few have proved perfectly hardy in the open, such as *O. Smithiana*, *O. Grahamiana*, *O. lobata*, *O. corymbosa*, and others. These when in full bloom are very attractive on the rockery, or in sheltered spots on the flower border. A few of the other kinds may be grown out of doors with a little management. The bulbs are lifted in the autumn, and when starting into growth, are planted in a cold frame in a rather stiff compost so as to enable

The many-flowered Wood Sorrel (*Oxalis floribunda*).

them to be lifted with good balls. They will commence to grow early, and as soon as frosts are over may be lifted and planted out in the beds or borders, where they will flower freely towards the end of summer. Where accommodation can, however, be given them indoors, I prefer growing them in pots. The majority are so well adapted for hanging baskets, edging stages, &c., that it seems somewhat strange they are not more generally grown. There are few of the *Oxalis* to equal the many-flowered Wood Sorrel (*O. floribunda*), represented in the accompanying woodcut. Its flowers vary in colour, being white, rose, yellow, and pink, its graceful drooping habit giving it a charming appearance. It produces its flowers in the greatest profusion all through the summer and early autumn months. K.

Ornithogalum arabicum—Fred. Capes, in THE GARDEN, June 25 (p. 574), asks about a plant allied to the Lilies. *Ornithogalum arabicum* is a very beautiful plant with pure white flowers which have a black spot in the centre. I have not found it a very satisfactory plant to grow, but perhaps my treatment of it may be wrong. I grew it in the border, but it did not prove hardy in this part of England. I also grew some in pots; they flowered

well, but the following year they never bloomed at all. The bulbs remained sound in the pots, but there was no growth whatever; the next year they started off strongly again. I would like to know whether this is a usual thing with this species; if so, it detracts considerably from its merits, and is very unlike the habit of the common Star of Bethlehem (*Ornithogalum umbellatum*), which is very free-flowering.—DELTA.

A beautiful Iris—I send you a lovely white Iris which is now blossoming on the hillside. It was discovered in an old garden in the north of Ireland, where the now wealthy industries of the neighbourhood point distinctly to the settlement in bygone days of French refugees. What fair legend may hang around this bridal flower we cannot say, but that it is ours to rejoice in to-day, we owe, no doubt, to some sweet memory of home, borne hence by an exile's hand.—ST. BRIGID.

* * * Flowers pure white, the falls broad, with a yellowish tinge. A very chaste and pretty flower.—ED.

Herbaceous Pæonies.—In THE GARDEN, June 18 (p. 554), R. Vesey complains that his Pæonies have died off. The reason of this is probably because they were planted in the spring instead of in the autumn. They must be classed amongst the hardiest of herbaceous plants. I planted in autumn last year thirty-six distinct species, some of them in several varieties, and we have not lost a single plant. Some of them being of extreme rarity, we took the precaution of planting the whole of them in some prepared soil, consisting of two parts loam to one of decayed manure. A spadeful or two of the ordinary garden loam was taken out, and in its place the compost was put in, and the plants firmly planted in it, a dressing of decayed manure being placed round the plants. Ordinary plants, such as can be purchased in the nurseries, take a year or two to become established. Mr. Vesey should see that his plants are well watered during the present hot weather. He says, "I have taken care in mulching and manuring them," &c. How was the manure applied? If it was dug or trenched into the ground it would be all right; but if holes were dug for the plants and partly filled with manure, perhaps not sufficiently decayed, and the roots of the plants were placed in immediate contact with the manure, this would be injurious.—J. DOUGLAS.

STOVE AND GREENHOUSE.

T. BAINES.

KALOSANTHES.

AMONGST greenhouse plants that flower profusely, *Kalosanthes* hold a high position. In the massive heads of highly coloured flowers which several of the varieties produce, they almost vie with the *Ixoras*, whilst being cool greenhouse subjects they do not require the heat necessary for *Ixoras*, and they are also easily grown, and may be readily increased. So readily do they strike, that the shoots if thrown down on any damp moisture-holding material, such as sand, fine ashes, or Cocoa-nut fibre, will produce roots freely. So free flowering are *Kalosanthes*, that small plants consisting of a single growth in little pots, struck the year previous, will bloom as readily as large specimens. As compact-growing, dense-habited plants, *Kalosanthes* are highly effective for greenhouse or conservatory decoration. The last-named structures are not, as a rule, the best places wherein to locate flowering subjects, even if only for the time they are in bloom, as they often are attached to dwellings, where external appearance is thought more of than the healthy growth of plants. Yet, even in houses of this character, where the amount of light which the plants receive is often very insufficient, there need be no hesitation in standing *Kalosanthes* whilst in flower. Another thing in their favour is that the best varieties bloom in summer after the bulk of the spring-flowering plants is over. The scent of the flowers is sweet and peculiar, and is liked by some, whilst others deem it oppressive, especially if a number of plants are

located in a house with the ventilators closed. Though, as already said, Kalosanthes are remarkably free bloomers, some growers do not get them to flower evenly, a portion of the shoots producing flowers, whilst others fail, although the plants collectively are strong, and give no indication of the cause of partial failure. Where this occurs, it is caused by the previous summer's shoots not being sufficiently matured, a condition that is indispensable to the production of an even display of bloom. The necessary ripening of the growth can only be effected by the plants being stood out of doors for a longer time during the summer than is requisite for most things.

Cuttings will strike at any time from early in the spring up to autumn. In the case of spring-struck plants they require to be grown on freely, so as to gain the necessary strength and maturity to enable them to bloom the year following. Another method is to take off strong shoots in August that have been grown on plants stood out of doors during the summer in the way described; they will root in a very short time, and so admit of their getting sufficiently established before winter. These late-struck cuttings must be put singly into small pots, drained and filled with a mixture of loam and sand. In this way the disturbance of the roots that occurs in potting off when several cuttings have been struck together is avoided. They will root in a greenhouse or cold frame, and require very little shade. As soon as they are rooted stand them in the open air, allowing them to remain out as long as there is no danger of frost. When well established move them into 5-inch or 6-inch pots, and during the winter they should be stood close to the glass.

Plants that have flowered two or three times often get straggling and bare of leaves at the bottom, and in this way have an unsightly appearance. The tops of such as these may with advantage be struck and flowered next year, and if larger examples are required than the single-stemmed plants, all that is necessary is to put several together in larger pots; this should be done in spring just as growth is about to commence. If to be thus managed it is better to keep them in 4-inch pots through the winter. When to be flowered several together in a pot the balls must be kept intact, using pots no larger than necessary. Young stock struck early in spring, or older examples that were propagated in the spring or summer previous, and which have been stopped and grown on with a view to flowering them in a larger state next year, should have been placed out of doors during the past month. So managed, every shoot that is strong enough may be expected to bear a head of bloom. When Kalosanthes are well grown, with the shoots strong and even, nearly the whole will flower. After the flowers are over, there is not time for new growth to be made that will bloom the following year. In the case of plants that have only produced a partial crop of flowers, if, immediately the bloom is faded, the shoots that have flowered are cut away and the plants are again turned out of doors, the portion that did not flower will gain enough strength to enable them to do so next summer. When they get tall and straggling, however well they may bloom, they do not look so well as younger examples that are close and compact; consequently, it is better to discard them and fill their places with younger stock, to keep up a supply, of which a few should be struck annually.

The old *K. coccinea superba* is a fine showy kind, but requires the growth to be thoroughly matured by lengthened open-air exposure to ensure its flowering well.

K. phenix and *K. frederick desbois* are both exceptionally fine, highly-coloured sorts.

K. miniata, another old and well-known variety, is a free bloomer, not requiring the growth to be so much hardened up to induce it to flower as the previously named sorts. The flower-heads are smaller and not so deep in colour. All the kinds mentioned should be out of doors whilst their flowers are opening, as if stood ever so near the glass in even the lightest of houses during this time they will be very

deficient in colour as compared with those that have developed their flowers in the open air.

BLANDFORDIAS.

THIS Australian genus of plants forms a tuft of Grass-like leaves, from the centre of which the flower-stems rise up to a height of a foot or two, and bear upon their upper portion a number of bell-shaped flowers of a wax-like texture. The colour of the blooms is red and yellow in varying proportions. These plants are now in full flower, and in this stage are remarkably pretty, in addition to which the blossoms remain in beauty a long time. Blandfordias are generally considered difficult to cultivate (indeed, they are rarely seen in a flourishing condition), yet I have never failed to induce them to grow and flower in a satisfactory manner, and that by no means under the best atmospheric surroundings, for in this neighbourhood the air is often heavily smoke-laden. They may be well grown in an ordinary greenhouse under the same treatment as Pelargoniums, except that they require to be shaded from the full rays of the sun, and succeed best if the atmosphere is kept cool and moist during the summer months. The compost we use for them is two-thirds good open peat to one of fibrous loam, and a very liberal admixture of rough silver sand. The plants are potted when they have done flowering, as then they become well rooted before winter. Owing to the Blandfordias requiring copious supplies of water when growing, and at the same time being very impatient of stagnant moisture, thorough drainage must be given. In potting a good plan is to place a little pure silver sand in immediate contact with the roots, which are few in number, but thick and fleshy, and which if injured in any way are very apt to decay. Should a root be bruised during the potting, it is better to cut it off altogether, otherwise the decay proceeding from the injured portion will rapidly spread upwards. During the winter these plants will only require sufficient water to keep the soil slightly moist, but as the spring advances more must be given, and as soon as the flower-stems make their appearance the supply must be still further increased. Blandfordias can be propagated by division, which may be effected when potting, or occasionally seeds will ripen. When seeds can be obtained, they will germinate readily if sown in pots of sandy peat and kept in a temperature somewhat higher than that of a greenhouse. Of the different Blandfordias in cultivation, *B. Cunninghami* and *B. flammea* are about the most showy; but *B. nobilis*, though smaller, flowers more freely than either. H. P.

SHORT NOTES.—STOVE AND GREENHOUSE.

Impatiens Episcopi.—This species is now flowering in one of the houses at Gammersbury Park. It is quite distinct from *Sultani*, very dwarf in growth, and of a free habit.—R. D.

Anthurium ferrierense.—This is a distinct kind worthy of a place in all choice collections of stove plants. It is of moderately vigorous growth, and associates well with *A. Scherzerianum* and *A. Andreanum*. The spathe is large and rosy pink; the spadix is erect and measures fully 4 inches.—T. W.

Cochliostema Jacobiana.—This beautiful plant we recently saw in flower at Kew. Both flowers and foliage are beautiful; the former are borne in branching panicles and are of a bluish violet colour, the large bracts being of a mauve hue. It is at once distinct and interesting.—T. W.

Dracæna Mrs. R. Turner.—This is a robust-growing variety which we saw recently at Messrs. Veitch's. The foliage is bold and handsome, the colour brownish, with a broad band of rosy pink at the margin; the young leaves are entirely pink, and it has the merit of colouring well even in a small state. E.

Trumpet Honeysuckle (*Lonicera sempervirens*). We saw a fine specimen of this climbing plant at Gammersbury House, and were struck with the density and distinct character of its foliage. The flowers are reddish pink, and borne in trusses about the same size as those of the common Honeysuckle, but not with such delightful profusion. It is not one

of the best of indoor climbers, but in a spacious conservatory or greenhouse room should be found for a specimen.—T. W.

Ivy-leaved Pelargoniums.—The vast improvement effected in the double-flowered forms of these Pelargoniums within the last few years, and the different uses to which they may be put, have been so frequently dwelt upon by various writers, that nothing more on that point is necessary, yet there are now so many varieties, some of which differ so slightly, if at all, from each other, that a few notes regarding the best of them may be of service. Having grown a great number, I have selected the following as the most desirable: Alice Crousse, deep magenta-purple, a vigorous grower, and very floriferous—indeed, one of the best of all; Emile Lemoine, bright cerise-scarlet; Jeanne d'Arc, pale mauve—form of the flower and habit of the plant very good; Isidore Feral, soft satiny rose, a variety of more trailing habit than most of the newer kinds; Madame Crousse, salmon-pink, a good and generally cultivated variety; Louis Thibaut, bright red; Madame Thibaut, a short-jointed, sturdy variety of a bright rose colour; the outside petals of this are distinctly reflexed, which gives to the whole flower a very uncommon appearance. Fürstin Josephine Von Hohenzollern—though this variety has such a cumbersome name, it is very beautiful, the flowers being bright red, shaded magenta, and very double. The other selected varieties are Madame Pages, deep lilac, feathered with a darker tint; Madame Jules Menoreau, rich bright rose; Sheipoo, bright carmine; Comtesse Horace de Choiseul, small, but double flowers of a pleasing shade of soft rose; Madame E. Gallé, almost white; Madame Thouvenin, bright carmine, a grand flower and in all respects a desirable variety. The above may be relied on as a good and distinct selection, while I have a number of new varieties under trial which may also be desirable.—H. P.

WORK IN PLANT HOUSES.

GREENHOUSE.—SOLLYAS.—Owing to many of the blue and purple-flowered old-fashioned plants not being now grown, there are wanting two of the most important colours. Amongst blue-flowered plants that used to be met with everywhere in cool plant houses, the Sollyas were conspicuous; their flowers, though comparatively small, are produced in such quantities as to have a telling effect. As roof-climbers—except for a small house—their slender habit of growth renders them less conspicuous than some things; for clothing a pillar they are better adapted. But to utilise the colour their flowers afford to the best advantage they require to be grown in pots and trained loosely as specimens; in this way they can be placed when in flower wherever they are most wanted. A few examples, such as can be grown in 10-inch or 12-inch pots, when in flower and mixed amongst other things in a greenhouse or conservatory, make a good contrast to the class of plants now usually met with. Sollyas bloom so freely, that they will flower whilst quite small. During their early stages, until the plants have got large enough to cover permanent trellises, it is best to train the shoots round a few sticks inserted in the soil. Young stock, the potting of which may have been deferred till after they had flowered, should, as soon as out of bloom, be at once shifted into larger pots. The plants are free rooters, and not by any means delicate or difficult to manage, but they do not require nearly so much pot-room as most climbers; consequently, it is well not to give too large shifts in the early stages of growth. Specimens that are now in 12-inch or 13-inch pots should have manure-water frequently during the whole time they continue growing; by these means they can be kept for years in a vigorous thriving condition, simply looking to the drainage at times to see that it is efficient.

PLEROMA ELEGANS.—The matchless shade of purple which the flowers of this plant possess admit of its being used in the same way as the Sollyas. Like them, it flowers in a small state. It is as readily propagated as a Fuchsia, and is easily grown. It is a summer bloomer, coming in sooner or later

according to the temperature it is kept in through the winter. I have had it in flower in June after it has been wintered at about 16° or 18°, but if kept during the dormant season with cool greenhouse stock the flowers do not begin to open before August or the beginning of September. By varying the winter treatment a succession of bloom may be had. The leaves do not bear full exposure to the sun, especially if stood near the glass; this being the case, a thin shade should be used from the beginning of June through the summer months. Until the flowers begin to open the plants do well out of doors, choosing a place for them where they will be shaded from the sun during the middle of the day. As soon as the blooming is over shorten the shoots back at once, removing about half the length of the preceding year's growth, and when they have started into growth give pots a size or two larger. The plant may be grown to a size of 4 feet or 5 feet through, but smaller examples are much more useful for greenhouse or conservatory decoration, and as it is grown quickly and is easily propagated, it is best to discard any that are getting too large. Cuttings made of the current season's shoots, consisting of two or three joints each, will strike in a few weeks if put in now. Put them singly in small pots drained and half filled with a mixture of sand and loam, the remainder all sand. An intermediate temperature is better to strike them in than more heat; keep moderately close, moist, and shaded from the sun. Stop the shoots as soon as they begin to grow. When the plants have attained a useful flowering size they will take manure water freely all through the growing season. The flowers, if cut when about half open, give an effect to a bouquet unsurpassed by anything I have ever tried. At this stage their lovely purple shade is unequalled.

PLUMBAGO CAPENSIS.—With the aid of this and the two plants already named much may be done to secure the required colours in cool plant houses during the summer. One of the best properties of this *Plumbago* is that it will flower freely whilst young and small. Cuttings struck twelve months since and grown on in 5-inch or 6-inch pots will produce a sufficient number of their large bunches of flower to make them useful. Even in this size they are effective when placed amongst other plants, and last for several weeks in bloom. The plant may be cut back freely, and also a good portion of the old soil may be removed without injuring the roots or interfering with the following season's bloom. By annually following this course the plants can be confined to pots of any size. Where large examples, say 5 feet through by as much in height, are wanted, proportionately more root room must be given. When it is necessary to confine the plants for several years to the smallest sized pots named, the shoots must be cut in each year to within two or three joints of where they were shortened to the first season after blooming; this may be done either as soon as the flowering is over or deferred until spring, a little before growth commences. When large specimens are wanted, 10 inches or 12 inches of the preceding season's growth should be left; in the case of these larger examples it is immaterial whether the cutting in is carried out immediately after flowering or in spring, but it must be borne in mind that plants that are cut back late in the summer cannot make very much growth before autumn; consequently less water must be given them during the winter months. This *Plumbago*, whilst in active growth, likes manure water, especially in the case of large specimens grown as climbers, and planted out in borders where the roots are much restricted for room. Small plants struck during the past spring should be encouraged to make as much growth as possible, as the amount of flower that may be looked for will be proportionate to the size and strength attained. Attend to stopping the strongest shoots of the young plants in question so as to keep them bushy. Where there is a deficiency of stock, cuttings may yet be struck; treated in the ordinary way they will root in a few weeks.

PELARGONIUMS.—The early-blooming varieties of the large-flowered section of *Pelargoniums*

will in most cases now be going out of flower, and should be prepared for heading down, for, though they will continue to bloom more or less so long as the plants are encouraged to make growth, it is not advisable to keep them blooming later, as if the cutting back is deferred, it will interfere with their early-flowering next spring. The large-flowered varieties of these plants require to have their wood well matured before heading down, as without this they do not break satisfactorily, coming with only a limited number of gross, over-luxuriant shoots. To hasten the ripening it is best to turn the plants out of doors, standing them where they will be fully exposed to the sun. Gradually reduce the water supply, giving no more than will suffice to prevent the leaves flagging. A continuance of this treatment for about three weeks will usually suffice to harden up the shoots sufficiently, when the wood will assume a brown colour. In cutting down it is necessary to be guided by the size of the plants; if young, and they are required to be grown larger, the shoots should be shortened so as to leave three or four eyes to each. If the plants are already large enough, a couple of eyes to each shoot will be enough to leave. In all cases the soil ought to be allowed to become dry before heading down, after which the plants should be moved to a cold pit or frame and syringed overhead freely each afternoon, but no water beyond this must be given until they have fairly started into growth.

FANCY PELARGONIUMS.—These do not keep on flowering as the large-bloomed sorts, and in most cases the plants will now require cutting in. With these it is not advisable to carry out the ripening process to the extent that is necessary with the large-flowered section; neither should the shoots be shortened so far, as if so treated the plants often break indifferently, or not at all; neither should the soil be allowed to get too dry. In other respects the fancies require to be treated as advised for the larger sorts.

KALOSANTHES.—Young stock struck from cuttings in spring, if not already moved into larger pots, should at once be shifted. Six-inch pots will be large enough for plants of this age. If the growth is well matured they will flower nicely next summer, and be found very useful for greenhouse decoration. If larger examples are wanted, three or four plants may be put together in pots proportionately larger. To ensure the growth being sufficiently matured to bloom well next season, the plants must be fully exposed out of doors in a sunny position during the summer and autumn, so long as there is no danger from frost. Larger specimens that have been grown on a year longer before allowing them to bloom must have sufficient pot room to keep them in a vigorous state, and in like manner have the benefit of the sun out of doors. Some of the varieties will flower without such a lengthened exposure in the open air, but the largest flowered sorts require to have their growth fully matured in this way, otherwise they produce very few flowers.

T. B.

Gloxinia with variegated foliage.—I have a seedling *Gloxinia* of the large-flowered strain raised here last year which has foliage prettily mottled all over with yellow. I would like to know if it is infrequent for these plants to sport thus. With the impression that it is, I have inserted a number of leaves as cuttings.—J. M.

Plumbago capensis.—This is still without a rival as a beautiful greenhouse climber, its pale lavender-blue bunches of bloom being so freely produced as to weigh the slender branches down. It makes a capital pillar plant, and the best way to see it to perfection is to train up the main shoots by tying them firmly to the supports, and then let the annual growth hang quite loosely. We have at present half a dozen plants in large pots treated in this way, and the effect is very pleasing. A good syringing to keep down red spider and plenty of root moisture are the chief requirements of this useful plant. It will grow freely in any good soil. A good companion plant is *Tecoma jasminoides*, that flourishes in the same house and makes a

pretty combination if the shoots are allowed to mingle together.—J. G.

KITCHEN GARDEN.

W. WILDSMITH.

CAULIFLOWERS.

IN early summer and late autumn we find Cauliflowers to be invaluable vegetables. They are desirable enough, indeed, all through the summer, but we usually have then a wealth of Peas, Beans, new Potatoes, and other toothsome vegetables, the which rank high in popular esteem; whilst all the Brassica tribe, and Cauliflowers especially so, are very liable to attacks of caterpillars, and even the nicest of heads are hardly pleasant eating when such livestock is abundant. The best months, therefore, for having a plentiful lot of Cauliflowers are those of May, June, September, and October. Happy, indeed, should we be could we have Cauliflowers in May; whilst if the weather be not too severe they may be plentiful enough in November, although as the winter approaches there is a tendency on the part of the heads to become rather strong tasted under the influence of frost. In the matter of earliness, probably none excel the Snowball, the which since its introduction into this country, curiously enough from Norway, is now offered under various designations; whilst on the Continent it is known as Extra Earliest Dwarf Erfurt, and is usually quoted at a remarkably high price, so sparse does it seed. Here at home, in the matter of seeding, it seems to be somewhat capricious, but much depends upon a knowledge of its peculiarities; still, a fair seed crop in this country is by no means difficult to obtain. Careful selection has led to the kind being produced with remarkable evenness and earliness. It is not desirable to sow the Snowball strain in the autumn, as the resting incidental to being wintered in a frame tends to induce buttoning. The best course is to sow seed in gentle warmth in January and keep the plants growing on rapidly, but near the glass, when large enough either dibbling up some 3 inches apart in a frame or else placing two plants into a 5-inch pot, and when these are strong turning them out on to a warm border, and, if possible, for a couple of weeks or so under hand-lights. In this way it is easy to have fine pure solid white heads for cutting from quite as early as late August-sown plants of the Early London would yield. Even earlier heads may be got if plants be put singly into 8-inch pots, and stood on the floor of a vinery. A second sowing in a cool frame, made in February or March, will give a good succession of heads as long as Cauliflowers may be desirable. Those who prefer big heads will do well still to sow the Early London if they can get a good stock of it; but the plants must be housed all the winter, needing considerable attention, and requiring numerous handlights or cloches if any quantity is grown. Cauliflowers demand quick growth to be soft and pleasant eating; hence the soil in which they are planted should be deep, well pulverised and manured. We have Cauliflowers under numerous names, but, after all, there are not many distinct varieties. Of these, however, none seem to be more useful or reliable than is the Autumn Giant, and no kind is so widely grown. So popular is it as a market variety, that some growers put out 20 acres of it at once, and yet we seem never to have too much of it. Of course, when it is in good form in the London market from home growth, any imported samples stand a poor chance. As the plants have a life so much shorter than other spring-sown members of the Brassica tribe, it is on that account all the more popular with market growers. Sowings of this invaluable sort can hardly be made too early in the open ground; indeed, March seems to be the favoured month, if weather and soil be favourable also. A second sowing in the month of May will give plants to turn in during November should weather permit. Of course, heading-in may be accelerated by close planting, and may be deferred by thin planting if the soil be good enough to induce strong growth. In private gardens this Cauliflower is too often made to produce heads

which are too large, for size and strong flavour are too often allied. A valuable addition to the semi-Cauliflower group of Brassica is the Self-protecting kind, for which, as well as the Autumn Giant, we have to thank Messrs. Veitch and Sons for introducing. Even the most determined pessimist will hardly deny but that, during the past twenty years, we have made considerable progress in Cauliflowers; indeed, more with these, perhaps, than with any other members of the Brassica family. A. D.

OVER-CROPPING CUCUMBERS.

I CANNOT agree with Mr. Muir in his remarks in THE GARDEN, June 18 (p. 565), on this subject; indeed, the idea of thinning Cucumbers is quite a novel one to me, and I have never found any ill effects from so-called over-cropping, even with the most prolific varieties. All that is required to keep the plants growing when a very heavy crop is hanging is plenty of surface-feeding and a little change in general treatment. I usually devote a small seven-light pit to Cucumbers. We commence cutting here the last week in March, and have plenty of fruit without any break until the end of October.

We have had recourse to exceptional feeding this season, for a variety on trial has proved wonderfully short-jointed and prolific, the majority of joints showing five fruit. We have not taken every fruit, but the proportion of loss has not been one in ten; there are plenty hanging now, and the plants are healthy and vigorous. The secret, if there be any secret in it, of keeping up a continuous supply of Cucumbers from one house or pit for some seven months in the year is to grow the plants along quietly in the early stages close up to the glass, avoiding excess of heat or moisture. I usually sow in Christmas week, plant out in the last week in January, and begin to cut during the last week in March. No shading should be used until the fruit is swelling away fast, but at this particular time if the crop is so heavy that there is scarcely any growth made, a little shading may be used, more heat and moisture applied, and plenty of surface-feeding to get the first batch of fruit off quickly. If the ordinary manure water is not a sufficient stimulant I have generally found a heavy top-dressing of horse droppings answer the purpose, and by these means sufficient impetus is given the plants to enable them not only to swell off the fruit, but to furnish them with a lot of young growth that will push away rapidly when the bulk of the fruit is gone. If the plants suffer at any time from neglect, the best remedy is to withhold the copious supplies of water the Cucumbers usually delight in, give a little shade, plenty of heat and moisture, and keep the surface of the beds moist to encourage root action. E. BURELL.

Peas.—After using every effort to raise early Peas so that gatherings may be made as soon as it is possible to obtain them, some dissatisfaction mingled with gratification is experienced when we find that those which were sown at new year in boxes, tended carefully with air, light, and other requirements, are no further forward in the middle of June than those which were sown during February in open borders. The latter are stronger, more productive, and resist the drought better than those sown under glass. We gathered the first pods on June 11. William the First was a few days only ahead of Sangster's No. 1, and several others are coming in together. The finest and most productive lots were those sown in rows where the soil was thrown out in lines right and left, 18 inches wide, and the seed covered with light rich soil. A number of rows are doing well which were sown on an early border in strips of turf and transplanted without any check to the roots by removal. A mulching 2 inches thick of loose soil thrown over the roots has done good service in preventing the destruction of the crop by drought, no rain having fallen in sufficient quantity since March to reach the roots of any of the crops. Proprietors put much value on the produce of their

own gardens, otherwise it is a simple matter to get abundant supplies of early Peas and other garden produce from earlier climes than North Britain (this is a Scottish midland county). In the villages and adjacent towns, Continental produce was carted about as well as exhibited in shops for sale weeks before any vegetables were fit for use in this part of the country.—SCOTT.

KITCHEN GARDEN NOTES.

MULCHING AND WATERING.—The prevalence of hot, dry weather has rendered both these operations imperative. Of course, the former lessens the latter, but all the mulching that could be given would not suffice without watering to keep such crops as Cauliflower, Celery, Peas, runner and dwarf Beans in vigorous growth. The hose has therefore been in full work, and we have abundance of Peas, Cauliflowers, Carrots, and Potatoes, whilst other crops are looking as vigorous as if the weather had been specially made for them. We have recently applied mulching to the last planted crop of Celery, and lately planted Asparagus and Seakale plots. Watering the two last is out of the question, and as they are not expected to be fit for use next year it will not be likely to permanently affect them should they suffer from drought. A thin sprinkling of salt has been applied over the mulching to keep down weeds.

HOEING.—Crops that it is inconvenient to either mulch or water are hoed as frequently as possible; amongst these are Carrots, Parsnips, Onions, Beet, Salsafy, Lettuce, Endive, and Potatoes. The latest and tallest haulmed kinds of Potatoes have all been earthed up. Earthing up of early and short haulmed kinds we cannot do, because between the rows we have planted autumn Cauliflowers, early Broccoli, Savoys, and Coleworts; besides, the practice is of no benefit to the crops; therefore such work as this must be accounted wasted labour. By persistent adherence to the above rules in regard to hoeing, weeds are never a serious annoyance to us, simply because they get no chance to develop, so that, apart from the benefit that the crops derive from frequent stirring of the soil, there is no exhaustion of it by weed growth.

PEAS AND FRENCH BEANS.—Other sowings of these have been made; of the former we have sown both early and late kinds. The early sorts are sure to do well, and, given a genial autumn, late sorts will probably be still better. The deep drills were, before the seed was sown, well watered, and after sowing another soaking was given, and were it not for the raids that slugs made on the young plants we should apply mulching at once; it is, however, such a convenient harbour for the pests that its application must be deferred till the Peas are about 6 inches high. The last sown are now being staked and mulched, and the crops of the earliest being now exhausted the ground will be cleared forthwith and recropped with early Broccoli. A south border now nearly cleared of early Potatoes is in course of preparation for French Beans, by being deeply dug and having applied to it a dressing of artificial manure. The last sowing of Runner Beans has been made and advancing crops staked, as also have all Peas that had attained 6 inches in height.

SPINACH, LETTUCE, AND ENDIVE.—The plot of ground cleared by digging up foreing roots of Asparagus, after due preparation by manuring and trenching, has been set apart for the crop of winter Spinach. The drills are already drawn, and as soon as we get a shower the seed will be put in. This is a crop that well repays the most liberal treatment and plenty of space. The drills ought not to be closer than 18 inches apart, and the plants when finally thinned not less than a foot. In an extra warm season this sowing may prove to be too early, and premature seeding result; it is therefore well to arrange for making another sowing about the 20th July. Lettuce we shall continue to sow in small quantities about every ten days till the end of July, and at that time we shall make a larger sowing of the Black-seeded Bath Cos for winter use. A couple of other sowings of Endive—now and in the middle of July—will be ample to keep up a

continuous supply of this salad during the winter. The last sowings of both Lettuce and Endive require thinning out, and if rain does not come soon, we shall have to water in order to draw the plants out easily, as they are already being injured by overcrowding.

GENERAL WORK.—Though so late in being ready, Asparagus was never more valued or more profitable, by reason of Cauliflowers and Peas being so late. Both are now plentiful, and we shall therefore discontinue cutting Asparagus. There are a few self-sown plants, and these with weeds will now be pulled up, then for this season will be ended all labour in regard to this crop. Turnips require thinning out and another sowing to be made. All the Year Round is, I think, the best variety for present sowing. Tomatoes need attention as to ties once a week, and those on walls will take any amount of water. We keep the shoots rather closely pinched back, and this has a tendency to make the plants more fruitful. An over-abundance of foliage or shoots prevents the proper colouring of the fruit, which can hardly have too much light and sunshine. Pick off the flowers of Seakale, Rhubarb, and Horseradish, and if the ground is not mulched it should be frequently hoed. As soon as rain comes plant out Broccoli and other winter greens, and meantime every spare piece of ground should be made ready for the same. Keep Vegetable Marrow and ridge Cucumber beds free of weeds and the shoots well thinned out. W. W.

GARDEN FLORA.

PLATE 603.

RUELLIA MACRANTHA.

(WITH COLOURED PLATE.*)

THIS genus of Acanthaceae plants as now constituted includes many species which are known in our gardens under the generic names of *Dipteracanthus* and *Stephanophyllum*, and comprises about 150 species, some of which are sufficiently showy to render them worthy of a place in any garden having the convenience of an intermediate stove. This statement is amply borne out by the coloured plate of the species we here give.

Ruellias are easily and quickly grown into good sized specimens. The soil for them should consist of an admixture of leaf-mould, loam, peat, and well decomposed (but not spent) manure, in about equal parts, adding to the whole a small portion of sharp river or silver sand. They strike readily from cuttings, and where moderate sized plants only are required, they should be renewed in this way annually, as the young examples retain their foliage better, and produce larger flowers than old plants. During the summer these young plants should frequently have the points of their shoots pinched out, in order to produce lateral growth, form bushy plants, and thus increase the number of flowering shoots. In the case of the winter-flowering kinds it is not advisable to continue this system of stopping later than the beginning of August. If, however, larger specimens are required than can be grown in one season from cuttings, the plants after flowering should be cut back hard; and as soon as the buds show the first signs of starting, the old soil must be partially shaken away from the roots and the plants repotted in fresh material, increasing the size of pot from time to time as may be requisite. The shoots must be stopped during the growing season, as previously recommended for young plants. An abundant supply of water is necessary; therefore the drainage must be kept open.

* Drawn for THE GARDEN in Col. Beldome's garden, Sispera, Putney, by Miss E. Lowe, Nov. 3, 1886, and printed by G. Severeys.

A few years ago Acanthaceous plants were more popular than they appear to be at the present time. The fact is, that although they are profuse bloomers, and many of them come into flower during the dull winter months, when, as a rule, bright blooms are not plentiful, these plants are useless for yielding cut flowers or for market purposes, as their flowers fall quickly, and even when growing on the plants they last a very short time. Nevertheless, for the decoration of the plant house they are extremely valuable, producing in succession a great quantity of their richly-coloured blooms. The following species of *Ruellia*, as winter bloomers, are well deserving of general cultivation:—

R. MACRANTHA, producing large trumpet-shaped flowers of a rosy purple, veined and streaked in the throat with lines of a deeper hue.

R. HERBSTI.—This plant is a most profuse bloomer, producing dense racemes of beautiful flowers of a rosy purple and white, whilst its leaves are streaked along the centre with white.

R. CILIATIFLORA produces funnel-shaped blooms of a bluish purple hue, and is perhaps more valuable for autumn decoration than winter.

R. PORTELLE is a free-growing and free-flowering and much-branched plant, bearing hairy, rosy pink flowers throughout the whole winter.

R. BAIKIEI produces dense racemes of bright scarlet tubular flowers of great beauty. It is a plant which requires less attention to stopping during the growing season, as it branches freely and naturally, but does not ascend quickly if the points of the shoots are pinched out. W. H. G.

FRUIT GARDEN.

W. COLEMAN.

FRUIT BORDERS.

MULCHING AND WATERING.—When writing some few months ago upon the value and importance of mulching, I did not at the time think a period of exceptionally dry weather, if not actual drought, had then set in. Such, however, was the case; consequently, the subsoil in this part of England having been deprived of a portion of its usual supply of winter rain commenced drawing upon the surface, now equally dry—certainly too dry for the roots of many trees and all succulent vegetables. Mulches, I stated, might be composed of various materials and be used to answer many, some of them directly opposite, purposes. The protective mulch for keeping out frost is good in its way, but just now, with the mercury standing at 80° in the shade, it is rather out of season, and may be dismissed for the present. The spring mulch for the preservation of moisture, combined with the inlet of warmth, this year has been a powerful host, and on cold soils might have been found quite sufficient for the season. Something more, however, now is needed, and the sooner it is applied the better will it be for fruit-laden trees in general, and newly planted ones in particular. Long litter, Moss, Grass from the lawns, old Mushroom manure, and solid manure, one or all, spread from 2 inches to 4 inches or 5 inches thick over the surface of fruit borders, will tell in several ways: first, in keeping or holding the water in suspension on application through the hose or otherwise until the ground can take it in; second, in preventing its evaporation on hot days; third, in drawing the roots to the surface and keeping them there; and last, but not least, in feeding when the dry heated atmosphere is taking moisture from the foliage so much needed by the fruit. Any of these materials used in plenty will form a non-conducting medium; but the best at the present time, no doubt, is rotten or half-rotten manure, which should be laid loosely over the whole

root-run and lightly covered with long litter, for the twofold purpose of preserving its stimulating properties, and, in the case of wall trees, maintaining a neat and clean pathway. Pyramids, bushes, and standards do not absolutely require the covering of litter, but, where plentiful, the two combined form a more complete and lasting mulch than one or the other separately. Whatever is used at this time of year, be it rich or poor, there must be no stint, otherwise the intense heat playing on the wall-path, say, of a Peach border, will very soon reduce the bulk to a useless quantity. In all cases where fruit as well as foliage is roasting against hot brick walls, old Mushroom manure or hotbed manure, not leaf-mould, stands first on my list, as it feeds the roots at a most critical time, and can be dug into the vegetable portion of the border afterwards.

Next as to watering, the non-professional with an unlimited supply of water at his command may say, why mulch at all where water is so plentiful? The question is easily answered, if it does not answer itself. One gallon of water passed through a good layer of manure is worth ten gallons poured over a roasting, sandy border, for it draws the roots upwards to the influence of sun, heat, and air; it maintains an evenly moist and growing condition of the soil, and it does a maximum of good at a minimum cost in time and labour. Water, again, varies in quality, and often carries away more than it deposits in the soil. Pure spring water, for instance, which we should prefer for domestic use, not only is cold, but it acts upon some, if not upon all, soils in a prejudicial way; therefore, unless well warmed and softened by exposure to the atmosphere, a minimum through the mulch will be found infinitely superior to the maximum without it. Assuming that no other water can be obtained, then the deeper and richer the mulch the better the effect, and more freely may it be used. The best of all water for horticultural purposes is that which falls from the clouds, but this is too scarce and precious for irrigating purposes. The next best is obtained from ponds or open tanks, and the nearest substitute for either is running water from rivers or brooks fully exposed to the sun. The proper time to apply water is after the turn of the day when the sun has lost its fierce power, as the foliage as well as the borders can then be bathed and revel in its refreshing influence throughout the night. The quantity, it is hardly necessary to say, should be sufficient to penetrate to the lowest roots; therefore, notwithstanding the fact that many trees may stand sorely in need of help, the best and proper method of applying it is one thorough soaking in preference to incessant dribbles as fleeting as they are misleading. Dull, cloudy, or even rainy days offer still better facilities for doing an immensity of good with the hose. Many people, finding the mercury on the decline, lay down the hose and push aside the barrel to make ready for the shower, which, while refreshing all Nature, may not penetrate half an inch beneath the surface. Instead of resting on their oars, advantage should be taken of this delightful state of the atmosphere, not for washing the foliage—Nature will do that—but for soaking the roots to their utmost depths, and so preparing the soil for the rain to follow.

Strawberry Black Prince.—I have managed to thoroughly connect the Strawberry season this year. The last batch of Sir J. Paxton in pots will be over in a few days, and by that time we shall pick quantities of Black Prince from a warm outside border. Vicountesse Héricart de Thury and La Grosse Suerée will not be ready for ten days, so the Prince is a valuable

variety, and until something new is raised to equal it in earliness and colour and superior in size, it is not likely to be ousted from collections. I do not know Pioneer; is it an improvement on Black Prince?—E. B.

THE STRAWBERRY.

In the spring I sent some notes on the Strawberry plants taken just as they had passed through the winter. The leaves of some of them were quite blasted and decayed from the effects of the keen frosty winds. I stated at the time that the crowns were good, and safely predicted that the loss of the leaves was immaterial, and the present state of the plants has verified our most sanguine anticipations. A quarter containing 936 plants, set out in August last year, is now a most interesting study to an ardent fruit cultivator. Beginning with what we have hitherto considered our best early variety, Black Prince, one plant only has died; all the others, without an exception, are each laden with fruit and healthy green leaves. By the way, this old variety was the only one attacked by mildew last year. The leaves were well dusted with flowers of sulphur, which destroyed the parasite on those particular plants, and it appeared on no others.

Pauline we have tried, and are now growing in different positions in the open garden. Mr. George Paul, who, I believe, introduced it, told me that it did best on a warm border, that it was a week earlier than Black Prince, but he could not recommend it for early forcing. Following his advice, we planted out some good plants on a border exposed to the south, and protected from the north by a wall 9 feet high. The fruit is now (June 18) ripe enough for the birds; it is of the largest size and of excellent flavour. I may add that every plant (with one or two exceptions) planted on the border is bearing fruit; whereas nearly half of those in the open ground are not so. The plants were all alike when put out. Did the warmer position promote an earlier and better ripening of the crowns? The evidence points very strongly in this direction, and suggests the importance of getting the runners layered early in small pots, to be planted out permanently in the open ground not later than the first week in August.

King of the Earlies is on trial with the others, and promises well. It is very hardy, fruitful, and free in growth. We will increase our stock of this next year.

Keen's Seedling has produced the most even lot of plants, only one having gone off, and that since the hot weather set in. This good old sort was raised about 1806 by Mr. Michael Keen, of Isleworth, from seeds of the large white Chili. It was the only variety saved from a numerous progeny, for the most part white, and not well flavoured. It has been grown under the name of Keen's Seedling, Keen's New Seedling, Murphy's Child, Keen's New Pine, and Keen's Black Pine. This is the only variety we have grown in pots for forcing this year, besides Black Prince. We grew with it for several years President, but this last-named excellent variety has not been found so satisfactory as a pot plant. As an out-of-doors variety, Sir Joseph Paxton has the best appearance at present; the plants have plenty of foliage, and carry an excellent crop of fruit. This variety we discarded from our garden of light gravelly soil, but here in a clay loam it is superior to President, which with us this year is not of very even growth in the rows. James Veitch, usually of good growth, is below medium this year; it suffered considerably in winter, but the cause of its not growing well is owing to the runners not being strong enough last year. Duc de Magenta is rather stronger in growth, and is a very free bearer. This and James Veitch are the only two Continental sorts we grow now, after trying many of them.

Mr. Radcliffe we have grown instead of British Queen; it is scarcely to be distinguished from that good old variety except by its more vigorous constitution; but even this distinguishing feature may not be apparent in all gardens. Frogmore Late Pine suffered most in winter, and it has taken

longest to recover; four plants have been killed outright, and many are weakly. Unser Fritz is a favourite here, but to do well it must be propagated from runners annually. They must be taken early, and be planted, if possible, not later than the first week in August.

The same remarks apply to the latest variety we have, viz., Loxford Hall Seedling. It has not suffered in the least, which is rather remarkable, seeing its parents La Constante and Frogmore Late Pine are not of very strong constitution. Instead of the usual litter caused by placing straw, short cut Grass, &c., round the plants to protect the fruit from injury by dirt, we place to them short sprays cut from the ends of Pea sticks; these are stuck into the ground close to the plants, and the Strawberries hang from the branches. We tried wire protectors, but did not find them answer so well as these sprays, which are obtained at no cost in most gardens. We use them for pot plants, and for outdoor work they answer equally well. We mulch the surface of the ground with short decayed manure, and water freely. A tropical summer and water freely applied suit Strawberry plants best. I advise getting in the runners as soon as possible, as it is best to make a new plantation annually. Plant on deeply trenched and well manured ground, doing the work carefully to avoid giving any check to the plants, as time lost at the first cannot by any means be made up afterwards.

J. DOUGLAS.

TO DESTROY ANTS IN VINERIES.

"W. G. G." appeals for help in this matter (p. 557). One almost wonders how they get there. Well-managed vineries are about the last places, as a rule, ants would choose to infest. The case is rather different with Peaches. As the latter approach maturity and diffuse their aroma, ants are attracted from afar at times, and prove as troublesome as they are mischievous; but ants, with all their faults, do not eat Grapes, and seldom trouble vineries.

All this, however, may be but poor comfort and of little use to "W. G. G.," and yet, if it helps him to find out how the ants get in, it will assuredly assist him in getting them out and in keeping them out ever afterwards. In ignorance of the entire case, I should predict that they get in through drought, and must be driven out and kept out through water. Ants will not care, in fact, to remain in vineries, in which every portion of the surface is kept sufficiently moist to sustain vigorous growth and keep down insect pests of all sorts. For example, a Vine border kept sufficiently moist on the surface to generate a genial moisture throughout the atmosphere and keep down the ravages of red spider would afford no foothold, resting-place, or breeding ground for ants. Should any of the latter exist sufficiently far from the roots to be safely dosed with boiling water, such radical measures will facilitate the clearance. But it is not essential to scald to get rid of them. Persistent waterings, repeating them several times a day, with clean water will tire the ants out. Of course, should the borders, as is most probable, be very dry, turn, if possible, a hose over them, and let the water run over them for six, twelve, or even more hours at a stretch. If applied with a heavy rose, so as to wet large portions, or the whole of the border at once, the ants will hasten to shift their quarters, bag and baggage, after a few floodings. Even should the Grapes be nearly ripe, still the ants may be watered out by constant sprinklings and waterings overhead. The work may be hastened through using guano or soot, or almost any kind of manure water, supposing the Grapes are green and the Vines in full growth, while doses of paraffin or other mineral oils, or sweet or linseed oil, also hurry the exit of the ants. These insects love a dry bed, and clean and sweet food and quarters; hence, the opposites of these will make them decamp.

In a few cases I have known a few hungry toads very helpful in the clearance of ants; but the toads are not always hungry, nor will they, as a rule, eat to order. But the moist state of Vine borders—most congenial to the toads—is most abhorrent to ants. Besides, the overhead sprinklings, &c., that

keep the ants in motion, tempt the toads to pounce upon them, for the latter only eat their prey when in motion. Hence, should "W. G. G." adopt our general advice of washing the ants out, he may also try the toad remedy under the most favourable circumstances and report the results through your pages. One caution I must give him in reference to these useful helps. Toads are very shy at first, and as their sight is sharp and keen, they will not feed when watched. When used to those that stir up their prey with the watering-pot, they lay aside their reserve and eat at a rate and with a voracity that will astonish anyone unacquainted with their active feeding habits and enormous appetites. Water and scald the ants out, disturb their layers, by deep hoeing or forking up, as often as may be, render these noxious by the application of pungent manures, and get an army of live toads to snap up the ants on the move, and soon there will not be one to be seen.

HORTUS.

FRUIT NOTES AT WYCOMBE ABBEY.

MR. G. T. MILES, who has filled the post of head gardener at Wycombe Abbey, High Wycombe, for forty years, is well known as a successful grower of fruit, and though by reason of the absence abroad of his noble employer, Lord Carington, he has, for the present at least, relinquished exhibiting, he still grows as successfully as ever, as anyone visiting the place at the present time can testify. The admirable condition of the gardens is one of the leading features of the place, and denotes the close and constant oversight of Mr. Miles.

There are two houses devoted to Melons, the vines bearing fine crops of fruit. The best varieties for general culture and for market purposes are Cox's Golden Gem, a very fine white-fleshed variety; Longlet Perfection, pale green-fleshed, oval in shape, and quite smooth on the rind; Eastnor Castle, green flesh, one of the very best, early or late; Scarlet Hybrid, scarlet flesh; and Hero of Lockinge, one of the best of the early sorts, and it is also useful for exhibition. The plants are all in a very healthy condition. As soon as the roots come through the surface, a top-dressing of manure from a spent Mushroom bed is applied.

Cucumbers are in excellent bearing, and succession houses are got ready as required. The two leading sorts are Improved Telegraph and Tender and True. There are several houses devoted to Peaches. In the earliest house the fruit of Alexandra, a noble Peach raised by the late Mr. T. Rivers from the Old Noblesse, was already gathered. Mr. Miles has a very high opinion of this as an early variety, and considers it quite a week earlier than Hale's Early. Lord Napier Nectarine comes in with the last named, and for early crops Royal George and Bellegarde are grown together with Elrue Nectarine. In the second house are Bellegarde and A Bee Peaches, Lord Napier and Elrue Nectarines. In the third and latest houses are Barrington, Bellegarde, Violette Hative, and Sea Eagle Peaches, also Lord Napier and Humboldt Nectarines. There are remarkably fine crops of Peaches on open walls, and, save here and there a little blister on the leaves, the trees are in excellent condition. Alexandra is also the earliest outdoor variety, followed by Early Beatrice and Hale's Early, the latter coming very fine on open walls. The second earlies are Grosse Mignonne, Royal George, and Stirling Castle. The latest are Sea Eagle, Nectarine Peach, which is regarded as a very fine late variety, and Lord Palmerston. The earliest Nectarines in the open are Violette Hative and the Stanwick Elrue, followed by Murrey, Handwick Seedling, Pine-apple, the latest of all being Stanwick, Albert Victor, and Victoria. The two last, and the Victoria especially, produce fine green fruit, and Mr. Miles states that he has no difficulty in disposing of these, as they are in great demand for sending abroad, being gathered just before they are ripe. No doubt something, and perhaps more than is generally supposed, depends upon the character of the stock upon which the tree is worked. There is one tree here of Lord Napier that quite fills a small house, and produces

every year wonderful crops of remarkably fine fruit. That this tree is on a good stock there can be no doubt. Fine crops of splendid Peaches are obtained every year from trees under glass. The trees are always syringed with rain water, a supply of which is in a tank within each house. This is necessary, because all the fresh water on the estate comes through the chalk, and if it is used for syringing it is found to contain a white sediment which marks the fruit. On outside walls half standard trees are planted so as to have the lowest branches 3 feet from the ground. The abbey gardens are situated on low ground and spring frosts are at times keenly felt. A few maiden trees are also planted every year against walls, and trained so as to get just the kind of trees required for any particular position.

The Cherry house was very interesting. The earliest variety is Early Rivers, a black kind, excellent in all respects, the fruit produced abundantly. A week later was Black Circassian, a variety that is here grown to perfection; the branches carried their rich-looking fruit in great clusters. Governor Wood and Elton are two excellent forcing Cherries, bearing capital crops. The trees are planted in good loam, and a surface-dressing of loam is occasionally given them. The house is started in January, the temperature being kept low at night and from 10° to 50° by day. Cherries want plenty of air to get them well flavoured. It is a critical period, when forcing Cherries, up to the completion of the stoning process, and then a freer course of treatment can be allowed.

Tomatoes are also largely grown. The earliest crop is obtained from cuttings struck about November, and succession crops come from seeds sown in January along with early Melons. Stamfordian and Hathaway's Excelsior are the two favourite varieties, the latter remarkable for its handsome shape.

Pine-apples and Figs are to be seen in excellent condition. Of the former, some excellent plants of the Queen variety were developing fine fruit.

R. D.

Apple Green Costard.—I have noticed with interest your comments in THE GARDEN on the beauty of different sorts of Apple blossoms. The largest and most beautiful Apple blossom with which I am acquainted (and I grow over 300 varieties of Apples) is that of a variety called the Green Costard: these blossoms are usually about 3 inches in diameter, and I have measured one as much as 3½ inches. I have often deceived people, even those who have a fair knowledge of flowers, as to its nature. The tree itself is a moderate bloomer, and a good, but not extra heavy cropper. The tree grows strong with stout downy shoots, and the Apple itself is a large green conical variety, not unlike Catshead, but more regular in shape; a very good culinary variety; in season from October to the end of December.—JNO. WATKINS, *Pomona Farm, Withington, Hereford.*

Shading Strawberries.—The latest crops of forced Strawberries are this year later than usual, and in ripening are likely to suffer from sunshine. Now, although the Strawberry likes heat when swelling and ripening its fruit, a roasting temperature tells most unfavourably on size, colour and flavour. I, who grow for profit and to whom bulk is of the greatest importance, have long made a practice of warding off hot sun at this season. Shade applied with care improves the weight and quality of the berries. Strawberries to command the best price in the market must be firm and of bright colour. Neither can be had when the fruits are exposed all day long to a hot burning sun. Plants growing in a bed of soil are naturally under more favourable conditions than when grown in pots, but even in their case the effect of a little shade is good. It is when the berries are beginning to colour that the plants are most likely to suffer from sun. Some kinds are more liable to burn than others, Sir C. Napier sooner showing signs of injury than any sort I know. I shade my frames with scrim canvas during the hottest part of the day. This year, owing to an unusually long period of dull, moist weather, the foliage became so flaccid, that when

the very hot weather came the plants did not seem to possess sufficient hardness to resist it. In a lengthened period of dull weather a little air on at night is very helpful to the plants. J. C. B.

Summer pruning of Currants.—Black Currants promise this year to be such a poor crop, that what few berries are set on the bushes growers are declaring will not pay to gather. That being the case, it seems as if an excellent opportunity is now offered to try the effect of summer pruning, and certainly as a rule the bushes need it. Generally we leave too much wood in our Black Currant bushes, and during the present summer, having no fruit to carry, they will make excessive growth. If that liberty to produce wood could be fully utilised by removing now the chief of the old branches and thus affording the younger and stouter shoots ample light and air, how those would plump up during the summer, and what stout buds would they show for next year's crop production. Probably pruning Black Currants is just now a question of time, but it is obvious that if relief be not given now, when it would do so much good, it will have to be given in the winter, when as relief it will come too late. No doubt the summer pruning of Currants, and of red ones especially, is excellent practice, but far more honoured in the breach than in the observance. As to styles of pruning, it is certain that in market gardens here, the hard or spur pruning is that most practised, for the bushes in the winter are merely some half-dozen stumps, but in the summer are invariably laden with heavy crops of fine fruit. That is the case again this year; whilst Black Currants are so thin, Gooseberries are but a moderate crop. The recent heat has promoted blight on the standard trees considerably, and yet a month must elapse ere a true line as to the year's fruit crop can be obtained. A. D.

— In reply to "J. G." in THE GARDEN, June 18 (p. 557), I would only say that what the practice of market-growers in his neighbourhood may be has nothing to do with the merits of this question. All I assert is, that a vigorous unpinched or unpruned Currant shoot, not being sucker, produces more fruit, and of as good quality, than a shoot that is pinched or pruned back, thereby removing the best fruit-buds, &c. "J. G." will never be able to produce a general example to the contrary. "J. G." regards it as "something new" that Red Currants should be left unshortened, like Black Currants. Can he, or anyone else, give an intelligent reason why Red Currant shoots should be shortened any more than Black ones? In habit they are both almost alike, and bear exactly in the same way when treated alike. Why, then, top the shoots of the one, and not the other? As to needing ladders to reach extension-trained Currant bushes, I did not know before that Currant bushes grow above their natural height, or could be finally kept much under it by any system of pruning. "J. G.'s" idea of putting more fruit into a shoot by denuding it of half of its best buds will require some establishing.—J. S. W.

Ornamental Apple blossom.—"T. W. G." gives us in THE GARDEN, June 18 (p. 555), a long list of Apple trees which flower more or less, but as to presenting any special guide in the selection of a few sorts which produce particularly effective bloom, the list is valueless. Apple bloom is wondrously like on most kinds, and on but very few sorts indeed does it stand out as exceptionally striking and effective. It is just those few of which we wish to know, and probably a list of twelve of the very best trees to include good habit of growth, average freedom in blooming, and richness or depth of colour in the flowers, would be all that could be specified, or indeed is needed. As a rule, the bloom in ninety sorts of Apples out of a hundred is so much alike, that only minute examination could reveal the difference. We want to learn of trees which stand out from all others as having special elements of beauty when in bloom. To give short selections of these would be of real service, whilst long lists of kinds which all know and grow, and know also to have no special effectiveness associated with them, render no aid. As a rule, the best decorative Apple trees are those which

have moderate and somewhat pendulous habits of growth. If, on the other hand, effect is sought for in fruit colouration, we must put aside habit altogether, and accept whatsoever Worcester Pearmain, Duchess Favourite, Hollandbury, Cox's Pomona, Manks Codlin, Emperor Alexander, and similar showy fruited sorts may offer. On the whole, having regard to the wealth of decorative trees we have, I do not think we shall take to planting Apple trees for such a purpose just yet.—A. D.

RED SPIDER.

THERE is much truth, probably too much, in "W. I.'s" pithy and pungent criticisms against sulphur fumes as a remedy against red spider. As frequently applied, these are not seldom useless. But, nevertheless, I believe they can be, and often, in fact, are, so used as to suffocate or destroy the spider. To do this, however, sufficient heat must be used so as to vapourise a portion of the sulphur. It must by no means be burnt, or the Vines and other plants will be seriously crippled or killed, whether the spider is or not. And it is difficult to define the process or result of vapourisation. Suffice it to say that this cannot be accomplished at ordinary heating temperature. Neither from smeared flues nor pipes will sufficient vapour of sulphur be given off, unless the temperature of these is specially raised on purpose. While I am unable to give the exact heat that may be safely used for this purpose, it may be stated that it must be sufficient to cause the vapourous fumes of sulphur to be produced and distributed at once. You may not only see them diffused, but feel their potency in the eyes and nose. "W. I." says he did not care to stay in the house with the sulphur fumes. Let me add that had those been made sufficiently potent he could not have stayed. Neither are fumes that we can bear without serious inconvenience likely to kill spider. It is even so with tobacco smoke, a far less subtle and powerful thing than sulphur fumes. The inveterate smoker has to leave the house long before the aphides fall in dead shoals on the floor, and such rough and ready tests are useful in the application of sulphur fumes to red spider. The leaves of Vines, Peaches, and Melons will bear much more sulphur in the air than we can, and most fortunately than red spider or any other insect pest can.

No doubt there are risks involved in vapourising red spider to death with sulphur fumes; but so there are in all other modes of eradicating the red spider, and also in letting it alone. For example, neither Vine nor Melon leaves thrive the better for being coated with sulphur on their under sides. I have seen such leaves shrivel up under fierce sunshine like parched paper, and the process of sulphur daubing, dusting, painting, is slow and tedious at best. Besides, sulphur seems at times too gross to get to close quarters with the spider. Has "W. I." never found colonies of the latter happily disporting themselves under their cloaks of sulphur? Vapourising is by far the speediest; possibly, also, the most effective way. It has doubtless killed some plants when overdone, failed to clear others of the pest when underdone, but it has also killed millions of red spider and delivered thousands of plants from their cruel ravages. Skillfully vapourised, sulphur is not only a remedy, but an antidote, and in this matter prevention is infinitely better than cure.

HORTUS.

Mulching of outdoor Figs. A curious sentence on the above occurs on page 558. As it is apt to mislead as well as confuse, you will probably allow me to call attention to it. "The thirty hours' rain which fell at the beginning of the month will have penetrated the borders, and a mulch of long litter, while letting in the sun-heat, will keep the roots sufficiently moist for some time to come." The words italicised do not express the truth, but very much the contrary. No mulch that will keep in the moisture, but must of necessity shut out the sun's heat in the same ratio as it conserves the moisture. And besides all this, the

mulching of outdoor Figs is wholly a mistake. It keeps the roots and the local atmosphere cool, while the great need of Figs in the open air is, give them all the available leaf that our climate affords; there is always moisture enough and to spare to supply all the needs of our Figs in the open. What they desiderate is more heat alike in the earth and the atmosphere, and it is physically impossible that either can be added to during our summer by means of surface mulchings of litter, long or short.—HORTUS.

SEASONABLE WORK AMONG FRUITS.

ORCHARD HOUSES.

ASSUMING that many of the early varieties of Peaches and Nectarines have been cleared of their fruit, and midseason sorts are continuing the supply, the first may now be placed at the coolest end of the house, where they can be copiously syringed without detriment to the ripening fruit. Here they may be regularly supplied with water of a stimulating nature or otherwise, according to the condition of the roots, the size of the pots, and the quantity of fruit they have carried. Maiden trees that have just finished their first crops will most likely require a shift into pots a size or two larger, and as these should be grown into the finest possible condition for next year's forcing the secret of success in a great measure depends upon potting early and getting the compost well filled with roots before the leaves fall. Although all the trees cannot be potted at one time, a start should be made as soon as the first batch is ready, and the better to prevent them from feeling the check which follows picking out the crocks and points of the roots, a close growing atmosphere under glass, if not in the same house, where they can be frequently syringed will set this matter right in a few days. Growing trees should have one good watering to settle the soil as soon as they are potted, but this must not be repeated to a saturating extent until the new roots are working freely; dryness or anything approaching it, on the other hand, must be avoided; therefore constant surface syringing being apt to mislead, a light mulch placed on the tops of the pots and a little loose litter cast in amongst them will be found a great help, not only to the roots, but also to the foliage, as it will absorb and in hot days throw off a steady supply of moisture. Newly potted trees, as a matter of course, should be allowed to make wood and leaves until they have re-established themselves, when pinching and ordinary treatment may be resumed. Older trees, which it may be desirable to reduce and return to the same sized pots, should be allowed to stand over until they have completed their growth and the foliage shows signs of changing. Their return to the house is not absolutely necessary, but a moist, temperate atmosphere favours rapid recovery.

The general house now replete with the best of the midseason and late sorts will now require heavy syringing twice a day, and many of the trees will take water equally often. Good mulching or rich top-dressings cannot be dispensed with, and the oftener the liquid food is changed the larger will be the fruit. Where the drainage from animal manure is plentiful, this forms the main staple, always in a diluted state, as serious mischief often follows overfeeding. Then, by way of change, weak guano and soot water can be used once or twice a week, the latter being alike applicable to the foliage and the roots. If well managed trees are kept clear of aphid until after the fruit is set, generous culture generally keeps them free, but should this or black fly appear, the usual remedy of smoking for the first, and dipping for the second should immediately be put into force. For spider there is no excuse, as the syringe, engine, or hose, in good hands, make their existence impossible. Airing is not less important than water and cleanliness; therefore it should be managed on a very liberal scale, especially through the early part of the day. Indeed, extreme lateness being the object, the ventilators need not be closed after midsummer. When stoning is safely got over, the final thinning

with a liberal hand, or otherwise, will determine the quality of the crop. Many growers leave a great deal more fruit on pot trees than is good for them, and in this way bring the orchard house into bad repute. Others, who can tell at a glance what each tree is capable of carrying, crop accordingly, and rest satisfied with a fair quantity of fine Peaches in preference to double the number of stones whose meagre covering of pulp is not worth eating. If Figs are grown in the orchard house they will require liberal feeding with diluted liquid, top-dressing with rich compost, and copious syringing twice a day. If in pots or tubs and space is contracted, the pyramidal form answers best, and pinching once may be necessary to the maintenance of a compact habit of growth. Figs require very little pot room, and often do well plunged or planted out in narrow shallow borders near the front lights where limited head-room necessitates the bush form of training. If left alone they soon become gross and unfruitful, but annual lifting and replanting in pure loam and old lime rubble will keep many of the moderate growers within bounds for a great number of years. The hardest varieties enjoy strong heat, and fruit best when grown in the hottest and brightest part of the house.

STRAWBERRIES.

I have often suggested the growth of good batches of the best late varieties for filling up the gap which so often intervenes after forced fruit is over. This year is not only a fortnight to three weeks later than usual, but the intense dry heat which set in before outdoor plants were fairly out of flower having already told upon the quantity, if not the quality, of early pickings, these sets of pot plants will be found unusually acceptable to those who have them. Free-fruiting varieties, also British Queen, are well adapted for this kind of work, and when it is borne in mind that pits or frames, unaided by fire-heat, will grow them to perfection, the veriest tyro must see at a glance that anyone having a few lights to spare may have fruit of the finest quality through May and the early part of June. The layering and potting of the plants which form this connecting link in no way differs from the ordinary course followed by Strawberry forcers, the main points being early runners, medium-sized pots, extra well crocked, and ripe single crowns by the end of October. When ripe and going to rest, the pots may be plunged in the open air certainly until Christmas, when, the pits being at liberty, they should be placed where they are intended to remain until the fruit is ripe. If partially plunged in old tan, leaves or the soil of the bed, ample room should be allowed for the development of the foliage in the spring, as lifting and replunging at that time not only makes work, but the operation disturbs the roots which have worked into the bed and are ready to feed the enormous crops they should be capable of carrying. Some successful Strawberry growers do not even go the length of potting up as for forcing, but plant out from 3-inch pots in August, lift and replant in the pits from February to April. Codding being no part of the programme, these selected plants, after being well watered home in the pits and protected from bad weather to give them a start, should have full exposure on all favourable occasions until they come into flower. At the present time we are gathering from plants so treated, and having nothing like ripe Strawberries out of doors, the fruit is especially useful.

Layering.—Where strong maidens were put out last August and divested of their flowers in the spring, good watering and mulching by this time will have produced a rapid growth of runners. These, for planting out, I peg down upon small pots, for forcing and late spring use upon 5-inch and 6-inch pots, and having plenty of water close at hand, in dry weather they are bosed every evening. As soon as the plants are well rooted they are detached, carried in, and arranged in the full blaze of the sun and watered after it has gone down without wetting the foliage. Potting by some is carried on until quite late in the summer, but ripe roots as well as crowns being imperative and cold seasons frequent, the safest course is preparation

for any emergency by starting early. The Strawberry is by no means fastidious as to soil, provided it is well pulverised, the reverse of light, and never allowed to feel the want of water. The best, however, is strong maiden loam capable of growing good stone fruits and Roses. This may require enriching or correcting with burnt earth or lime rubble in preference to solid animal manure, which attracts worms if it does not induce sourness, and it should be well rammed into the pots when dry—no difficult matter just now, as nothing would please me better than spending my jubilee beneath an umbrella. When light, poor soils require correcting, sun-baked and finely broken marl, bone-dust, and a little very old cow manure rubbed through a sieve will give stability. Strong liquid from the manure-tank poured over the heap is a great help, and the latter in a diluted state may be used occasionally when the plants are growing freely. When young plants are transferred from 3-inch to the fruiting pots, the foundation for the little balls should be well rammed to prevent them from settling and strangling. They should be thoroughly moist at the time and arranged to admit of a good half-inch of compost over the surface. When the runners are pegged down upon the fruiting pots, danger from sinking or strangling is avoided, as each crown, like an enlarged fruit bud, sits upon the surface—the best of all positions for hardening and ripening.

PINES.

When the compartment devoted to the first batch of Queens has been cleared of fruit, a favourable opportunity for a thorough cleansing must be taken advantage of. Woodlice, crickets, and cockroaches, which increase rapidly and often injure the fruit by eating the pips, may be kept in check when the house is occupied, but nothing short of a complete clearance of the plunging material, scalding and dressing the walls with hot limewash will thoroughly eradicate them. When these irregular opportunities offer, not only in Pine houses, but in every house and pit heated by hot water, cleanliness should be the first step in the preparation for succeeding crops. The old and tainted material having been destroyed by fire, or taken quite away from the garden, the pit must be refilled with fresh tan or leaves, which will require some little time to ferment and settle. When the heat becomes steady, the plants, be they successions or fruiters, should be selected, top-dressed, or potted as may be found necessary, and plunged lightly at first, as it not infrequently happens that the slightest disturbance at this time of year renews violent fermentation. Unless we have a great change, fire-heat in a newly renovated pit will certainly be unnecessary, but the plants having been kept well up to the glass it will be wise to shade for a few hours through the hottest part of the day, not only to preserve the foliage, but also to keep down the bottom heat. Air and moisture, it is hardly necessary to say, must be on a scale suitable to the requirements of the plants, and early closing with a sharp rise from sun-heat under any circumstances will be advantageous. If the rearrangement of this pit favours the clearance and cleansing of another, a busy time must not be the excuse for allowing the opportunity to slip, as time in the long run is saved, and plants of all kinds by their health and vigour show that a complete change is good for them.

Fruiting houses.—The plants in this structure will require plenty of atmospheric moisture in preference to overhead syringing which enlarges the crowns, and careful attention to watering with weak stimulants, as too much water kills the roots and produces black hearts, whilst too little induces premature ripening. Because the Pine does not soon suffer in a close house, the baneful practice of giving water in small quantities to keep want away is frequently followed; but this is a great mistake; either the plant does require water, or it will do without it; therefore, a full supply or none at all should be given. When the fruit has attained full size and there is an indication of changing colour, water may be withheld, and the better to retard any particular Pine, the pot and plant may be moved bodily to a freely ventilated early vinery,

where the dry atmosphere and partial shade will favour perfect colour and flavour.

Young stock in pits and frames is now growing freely, and, provided this brilliant weather continues, will soon be fit for a shift into larger pots. When a proper degree of heat is maintained by fermenting materials alone and the pit is closed early with moisture, suckers fill their pots with roots in an incredibly short time, and often require shifting before their broad, stocky leaves indicate their condition. The only drawback to frame-struck plants is the danger of a check from removal to more airy succession pits; therefore to avoid this, they should be returned to the frame for a time after potting, and gradually inured to more light and air with a minimum of shade before they are transferred.

POT VINES.

When pot Vines have been cleared of their fruit, they should be turned out into a warm sheltered corner to harden off, and if not wanted for any other purpose, they will form excellent subjects for planting against old trees or buildings. The majority of these I know are thrown away, but the sorts usually forced, including Hamburgh, Madresfield, Foster's, Buckland Sweetwater, and Royal Muscadine, are not only hardy and ornamental, but quite capable of giving good fruit when well managed upon warm sunny walls and gables. When the house has been thoroughly cleansed and the bed levelled down, it cannot be better employed than for ripening off the pick of the batch intended for next year's forcing. Always assuming that these Vines are not allowed to root through, there will be no difficulty or danger attached to their removal from an inferior to a more suitable structure. If the place they occupy is good enough for the finish, this labour will be superfluous, but there are few gardens in which a little additional room is not beneficial to pot Vines in all stages. Whether they are moved or not, the pots should be raised out of and placed upon the surface of the bed, as ripe roots are quite as valuable as ripe wood. When they have completed their growth they will require a free circulation of air, a good supply of water, and a daily syringing until the foliage begins to change colour, when shutting up with dry sun-heat will ripen the buds and form the germs of future bunches. If all the main leaves on the lower parts of the young rods are sound and good, the laterals may now be pruned back to the fruit-producing buds, but on no account must this be done where the leaf has been lost, as the removal of the next best substitute, the first and only leaf on the lateral, will prevent the bud from drawing the nourishment still necessary to its perfect formation.

Vines from eyes intended for cutting back or planting out next season should be shifted into 6-inch to 8-inch pots before the balls become root-bound. Young Vines will grow in almost any free, sweet soil, but the compost which suits them best is made by mixing light, rich turfy loam, bone dust, and burnt earth or lime rubble together a week or two before it is wanted for use. Into this, when the balls are thoroughly moist, pot firmly, replunge for a short time to give the roots a fresh start, and when they have recovered from the check, gradually draw the pots to the surface of the bed, where they may remain until they require more head room. As soon as there is danger of the young foliage obstructing the light, a batch of the earliest and best must be drawn out and placed in a light house where they can have more air and a temperature rising from 60° at night to 75° or 80° by day, good syringing, and plenty of water. Stout, short-jointed canes being the object, remove all laterals at the first leaf and pinch the points of the young canes when they have made 6 feet to 8 feet of growth, more or less, according to future requirements. Weaker and later Vines intended for cutting down to a single bud may be pinched when they have grown 4 feet, and the pots in which they are grown need not exceed 6 inches in diameter. W. C.

The protection of Figs.—Our wise and genial weekly instructor and my good friend, Mr. Coleman, seems rather to misunderstand the spirit and drift of my remarks on this very interesting and impor-

tant practical subject. He issued a challenge to all non-protectors of their Fig trees to write down their condition in THE GARDEN, and promised, in advance, to accept the facts as decisive of the wisdom and necessity, or otherwise, of protection. I sent facts and Fig wood in response (see p. 506) merely to show that Figs were hardier than many supposed, and without the slightest intention of finding fault with our friend Coleman's teaching or practice, which we all know to be of the highest order. As Mr. Coleman has made a comparison between Tea Roses and Figs, I may add that I think the former, with the exception of such hardy varieties as Gloire de Dijon, are much more tender than Figs. Then, too, as to the latter, I should be glad to have Mr. Coleman's opinion as to one material element in the hardiness of the Figs noted and described by me—viz., their starving regimen.—D. T. F.

FERNS.

W. H. GOWER.

THE WEST INDIAN FAN FERN.

(RHIPIDOPTERIS PELTATA.)

THIS very elegant Fern is nearly related to the genus Polybotrya, although it differs in size from any member of that family. It is a native

The West Indian Fan Fern (*Rhipidopteris peltata*).

of Peru, Mexico, Brazil, and several of the West Indian Islands. Two other species of this genus are recorded, *R. fœniculacea*, from Ecuador, and *R. flabellata*, from Peru and New Granada. The chief points of difference of these, however, lie in the more or less finely-cut ramifications of their infertile fronds.

Our illustration is an excellent representation of a barren and fertile frond of this species, but it does not render an idea of the exquisite beauty of a well-grown specimen of the plant. It has a slender, creeping rootstock, and produces its fronds in abundance in the temperature of a cool stove, the barren ones being the more numerous. These are about 6 inches high, several times dichotomously forked, somewhat coriaceous in texture, deep green in colour, and very persistent. The fertile ones are orbicular, more or less bilobed, deep green above, the under side covered with sori, which in the

young state are black, changing to bright brown when ripe. These fronds are sparingly produced and are very fugitive.

This plant is admirably adapted for covering a boulder of sandstone or the dead stem of a Tree Fern. When once established in such situations it quickly clothes either with an elegant drapery of green fronds. Smaller, yet handsome, plants of this species may be grown upon a small block cut from a Tree Fern stem and suspended from the roof in a shady situation, or even in a Wardian case in the dwelling-house; but in the last-named place, growth, as a matter of course, will be much slower, and the fronds produced somewhat less in size. A little Sphagnum Moss should be fastened about its root-stocks, in order to assist in keeping them moist until the fibres have penetrated the block, when all that is requisite to keep the plant in vigorous health is an abundant supply of water. Treated as a pot plant this species seldom thrives for any length of time, as it appears to dislike its roots being confined in soil.

SCHIZOCLENA SINUATA.

THIS is a remarkable little Tree Fern, belonging to the tribe Cyathea. A few species constitute the genus, which are characterised by their sori being situated on the middle instead of the forks of the veins. This plant is peculiar to the island of Ceylon, but even there it is by no means plentiful. It grows in dense shady woods on the mountain-sides, the places where it is found being comparatively cool, while outside the woods the temperature ranges high. It is perhaps the smallest member of the Tree Fern family in existence, whilst it is dissimilar from all, inasmuch as it bears simple fronds. The stems seldom attain a greater height than 3 feet or 4 feet, and are as slender as an ordinary walking cane. The fronds are simple, spreading, forming an umbrella-like crown, from 1 foot to 2 feet in length, and from 1 inch to 2 inches in breadth, tapering at each end, somewhat thin in texture, and bright lively green in colour. This species was first introduced in a living state about the year 1862, but it has never become plentiful, which is much to be regretted; indeed it has not hitherto long survived after being imported. This, however, may be more the result of circumstances than from any peculiar difficulties attending its cultivation. In the first place, the majority of the stems sent to this country have been from 1 foot to 3 feet high, and which having nearly arrived at maturity, would soon have died had they been left intact in their native habitats. It is therefore no wonder that these slender, wiry stems seldom develop fronds for any length of time after the check they must have received by the destruction of the roots, arising from removal and during transit. It would give Fern growers at home greater chances of success if younger plants were imported. It has hitherto been the custom to grow this plant under a glass case, but from personal experience with it I am fully convinced it would thrive better in the open fernery, if the atmosphere was kept fairly moist and the situation chosen for it heavily shaded. It should be potted in peat and Sphagnum Moss.

W. H. G.

PROPAGATING.

ACACIAS.—This pretty genus of trees and shrubs, mostly natives of Australia, and valuable here for their free-flowering qualities, are usually raised from cuttings, and though they take some little time to root, there are many other subjects far more difficult to strike. In most cases the plants that flowered in the spring will have started into growth some time since, so that the young shoots have already lost some of their succulent character, and when this happens it is just the time to take the cuttings. They will require to be kept very close till rooted, and on that account should be either confined in a close case within a propagating house or placed

under a bell-glass. In either case the pots prepared for their reception must be well drained and filled firmly with soil passed through a sieve with a quarter of an inch mesh. A very suitable compost is two parts peat to one each of loam and sand, the whole being well incorporated together. After pressing the soil down firmly a space should be left at the top for a layer of clean silver sand. The cuttings are better if selected from the small minor shoots in preference to the stout, succulent ones, as these last are liable to decay. A length of 2 inches to 4 inches is very suitable for the cuttings, the first-mentioned size being quite large enough for the small needle-leaved kinds, while the larger ones, such as dealbata, affinis, and that type, must be about 4 inches long. When the bottom leaves are removed the cuttings must be dibbled in firmly (guarding against overcrowding), and after this a thorough watering given. The propagating case prepared for their reception may be in a structure kept at an intermediate temperature, and if put under bell-glasses the same conditions will suit them, or they may be stood in a cool and shaded part of the greenhouse, where, however, they take a longer time to root than if assisted with a gentle heat. A good plan with those that are under bell-glasses is to keep them in a greenhouse temperature or in a cool frame till callused, and when that takes place, if they are then removed into a gentle heat, they root quickly. When the cuttings begin to grow, then the bell-glasses may be tilted to allow of a circulation of air, and after a time removed altogether. In selecting a place for the cuttings after insertion, it should be borne in mind that if so situated that they do not dry very quickly, the chances of success in striking them are greater than if they constantly required watering, as this last frequently leads to decay. It is by no means necessary to propagate all the Acacias in this way, as seeds of many of them can be obtained, but where free-flowering specimens in a small state are needed, plants raised from cuttings are preferable to seedlings, though if required for roofs or pillars, these last, from their more rapid growth, are the most suitable. Seeds of Acacia imported into this country from Australia generally arrive in good condition, and should be sown as soon as possible after being received. If they appear to be very hard and dry, a good plan is to soak them in slightly warmed water for twenty-four hours, as the germination is greatly assisted thereby. The seed should be sown in a mixture of loam, peat or leaf-mould, and sand, and if kept fairly moist will soon germinate. When they commence to grow, the cotyledons will generally be supported on long, naked stems, which at the first potting should be buried nearly to the seed leaves, otherwise they are liable to topple over and decay. The potting off should be done as soon as the first leaf, independent of the seed leaves, is developed.

ORANGES.—Small Orange plants when in bloom are very popular and by no means difficult to obtain, yet as cuttings do not strike readily and seedlings must reach a considerable size before they flower, it is necessary to graft shoots from a flowering specimen on to young plants raised from pips. If the stocks are in a free and healthy condition, a union will soon be effected, as the bark then readily unites. Grafting may be carried out at almost any season, but just now is about the most suitable time. The scions should be clean, well grown shoots almost ripened, and the stock one whose bark has not yet reached that rugged character common to old plants. Side grafting is the method generally employed, and it may be carried out as near the ground as possible or at a sufficient height to form a small standard, according to the wishes of the operator. If the union be neatly effected and the graft tied securely in position, no clay nor wax of any kind will be needed, provided the plants are kept close till a union takes place. By these means one is able to watch the progress of the operation, which is not the case where the point of union is entirely hid from view.

ROSA RUGOSA.—This Rose, which forms such an attractive feature at the present time, will strike fairly well from cuttings put firmly in a border

during the autumn months, but a very good way to increase it is, if an established specimen exists in a position suitable for the operation, to layer the branches, for those treated in this way during the winter are already throwing up shoots in all directions, and where cut, the stems are now beginning to root. The white variety being as yet much scarcer is sometimes budded, but in this case suckers from the stock are often a nuisance, and it is more satisfactory when struck from cuttings or layers. Seeds take a long time to germinate, which they do very irregularly, but in the case, at least, of the red variety they perpetuate the same kind.

ROGIERA GRATISSIMA.—This pretty greenhouse-flowering shrub, which many fail to strike in a satisfactory manner, can be rooted without difficulty from cuttings, provided the suitable treatment is accorded them. In a greenhouse temperature this Rogiera will be now in full growth, and this is a suitable stage to take the cuttings. The shoots chosen for this purpose should not be the terminal ones, but the minor side branches, as they strike better than the stout ones. A length of about 3 inches is very suitable for the cuttings, and when the bottom leaves are removed they must without delay be dibbled into well drained pots of very sandy peat. The soil for the purpose must be pressed down firmly, and before use passed through a sieve with a quarter of an inch mesh, as a rougher compost would interfere greatly with the chances of success. They must then be placed in a close case in the propagating house, or, failing this, under a bell-glass in the cool end of the stove, but they must not be plunged in bottom heat till a sufficient length of time has elapsed for them to callus, when a little additional warmth will hasten the formation of roots.

GREENHOUSE AND STOVE CLIMBERS.—Nearly all these will be now in active growth, and therefore good clean shoots suitable for cuttings are readily obtainable, and in most cases will strike root without difficulty. The cuttings of *Passifloras* and *Taesonias* strike quickly and grow away rapidly, while plants raised in this way are preferable to seedlings, for they are more floriferous, besides which they can be relied on to perpetuate any particular variety. One caution to be observed is that climbers near the roof are sometimes infested with red spider, and if there are any on the leaves when put in a propagating case they quickly spread; therefore great care must be taken that they are thoroughly clean before being inserted. T.

ORCHIDS.

W. H. GOWER.

THE ERECT-FLOWERING SACCOLABIUMS.

THESE comprise a few small-growing, free-flowering plants, which form a very natural group, and they specially recommend themselves to those having but limited accommodation. As before remarked, these plants are dwarf in habit, and consequently succeed best on blocks of wood or in baskets; the latter are preferable, as treated in this manner they can be suspended from the roof near the glass, and thus obtain all the benefit from sun and light, conditions under which they thrive admirably, although they must be screened from the sun during the hottest part of the day in summer. The baskets in which these plants are grown should have a layer of nodules of charcoal at the bottom to ensure thorough drainage, and the Sphagnum Moss surrounding them should be alive and sweet, but very little of this material is necessary, as they do not like their roots to be much confined. They enjoy strong heat and an abundant supply of water during the growing season, but after growth is finished, a decided period of rest is necessary to produce bloom; during this time, however, the leaves must not be allowed to shrivel, as if the drying system is

carried out so severely as to cause this, it is difficult to restore the plants to a healthy condition; moreover, the loss of leaves which ensues from the shrivelling system greatly disfigures the plants, and as they make their leaves slowly the disfigurement remains an eyesore for several years. The safest plan to adopt in resting these *Saccolabiums* is to reduce the temperature to about 60° during the winter months, and only give a little water from time to time just to keep the plants from being injured by drought.

S. AMPULLACEUM is a handsome kind: the leaves are two-ranked, somewhat short, truncate at the ends, and pale green, sparingly dotted with dull purple. The racemes are produced very freely, and are some 4 inches or 5 inches high. The flowers are wholly delicate rosy magenta, saving the base of the small lip, which is white; these appear in the spring and summer months, and last several weeks in perfection. It is not desirable to allow the blooms to remain too long, as the plant is so floriferous that there is danger of death from exhaustion. The variety *moulmeinense*, introduced by the Messrs. Rolleston, is a stronger growing plant; its leaves are more profusely spotted, and the racemes of bloom are longer, and the individual flowers are larger and of a rich deep rose colour. Moulmein.

S. CURVIFOLIUM.—The leaves of this plant are narrow, deflexed, thick and fleshy in texture, and pale green. The racemes are 6 inches or more high, very dense, flowers bright cinnabar-red, lip tinged with orange and bearing two orange spots at the top of the spur-tube. In the variety *luteum* the flowers are clear yellow, which renders it very desirable as a contrast; it is, however, still very rare. Both forms bloom during the late spring and early summer months.

S. CELESTE.—This is a plant of quite recent introduction; it appears to be much stronger in growth than the last named species, and its erect spikes are a foot high, bearing quantities of flowers of an azure blue. It has hitherto only flowered in Sir Trevor Lawrence's collection; but as a fine consignment has recently been received, we are likely to see this charming plant frequently.

S. HENDERSONIANUM.—The leaves of this plant are about 6 inches long, about half-an-inch broad, tapering to a point, and bright green. The racemes are nearly 6 inches high, very dense, flowers bright rosy red with a narrow white lip. Borneo.

SHORT NOTES.—ORCHIDS.

The **Lizard Orchis** (*O. hircina*) which I send is, I think, a rare British species almost extinct on the chalk. St. Brican.

* This British plant is very rarely now to be met with. It is interesting, but not pretty, and the smell is disagreeable.—E.

Oncidium nigratum. This is a most distinct and interesting species with panicles about 2 feet long, which bear small, well-coloured flowers. The sepals and petals are crisp white with almost black blotches, and the yellow lip is spotted with light cinnamon. It is in flower at Messrs. Veitch's.—E.

Oncidium lanceanum. This distinct species is flowering at Messrs. Veitch's. The spike attains a length of from 12 inches to 18 inches, and bears a number of richly-coloured, fragrant flowers of striking beauty. The sepals and petals are thickly spotted with rich brownish-crimson on a yellow ground; the lip is rosy violet, the base of a deeper shade of the same hue.—It is not often seen in such healthy condition as at this nursery.—T. W.

Masdevallia demissa. This is a very pretty and free-flowering new species recently introduced by

Mr. Shuttleworth from Costa Rica, and is now flowering in his nursery at Clapham. It belongs to the coriacea section, the flowers being reddish crimson in colour, the tail-like ends of the segments yellow.—W. H. G.

Scutellaria Steeli.—We saw this handsome Epiphyte in flower recently at Mr. Bull's. The fragrant flowers are of large size, the sepals and petals yellow, blotched with brown, the bold lip being striped with brown on a ground of the same hue. The whip-like leafage gives the plant a singular and distinct appearance.—E.

Epidendrum tovarense.—This plant is now flowering in Mr. Shuttleworth's nursery, and, although not long established, it appears likely to prove a welcome addition to the paniculate section of this genus. Its flowers are pure white, with a honey-like fragrance, and are borne on branching racemes. It requires quite cool treatment.—W. H. G.

Madeira Orchid (*Orchis foliosa*).—This is an excellent plant for growing in pots. There are at the present time several excellent specimens in full bloom in one of the pits at Chiswick. Plenty of water during the growing season and protection from heavy rains and severe frosts are necessary to secure an abundant leafage and profuse display of the rich purple flowers. T. W.

Aerides crassifolium.—This Burmese species numbers among the most beautiful of the *Aerides*. It is of neat, compact habit, and has dark green, leathery leafage, which harmonises well with the pendent racemes of delicately fragrant flowers. These are very large and pale amethyst in colour; the lip highly developed, and forming a characteristic feature. It is one of the largest flowered of the genus. When cultivated in a basket and placed near the light it makes a sturdy growth. It is in bloom now at Mr. Bull's.—C.

Lælia purpurata.—Like *Cattleya Mossiae* and *C. Mendeli*, this varies considerably in depth of colouring, some forms being richer than others, and though the varieties are many in number, comparatively few are of inferior quality. We saw a fine variety recently at Messrs. Veitch's, the lip being of a rich claret-purple, and at Mr. Bull's a form called *versicolor* is in bloom. This is one of the most distinct we have seen; the petals are flushed with rosy purple of nearly as intense a colour as the lip.—T. W.

Masdevallias of the *Harryana* section are well grown and flowered in the collection of Mr. Hyatt, Hethersett, Streatham, in a very low temperature. Mr. Luff says "he finds them grow better and flower most profusely in rather small pots." This statement is well borne out by the numbers of flowers now expanded, the varieties varying much in size and intensity of colour. In the same collection are also flowering good forms of *M. Veitchi* and *M. ignea*, the latter now bearing its second crop of flowers this season, which is said to be characteristic of this species at Hethersett.—W. H. G.

Cypripedium Curtisii.—This rare and beautiful Lady's Slipper is now flowering in Mr. Williams' nursery at Holloway. It appears to have some affinity with *C. ciliolare*, but is very distinct from that plant, or, indeed, any other of this now numerous genus of Orchids. The leaves are broad, the ground colour dull green, boldly tessellated with dark green; flowers large and handsome; the dorsal sepal is light green, bordered with white, and veined with dull purple; petals are deflexed, with recurved tips, greenish white, veined with purple and covered with magenta-purple dots, the edges densely fringed with short black hairs. It enjoys strong heat and moisture. W. H. G.

Cattleyas.—Various species and varieties of this genus are in great beauty in Mr. Laing's nursery at Forest Hill, C. Mendeli and C. Mossiae being, however, on the wane. These are being succeeded by numerous forms of *C. Gaskelliana*, which is a fine summer-flowering form. The most conspicuous just now, however, is *C. gigas*. A fine form of it is bearing flowers upwards of 9 inches across, the sepals and petals large and full, rosy lilac, lip dark violet-purple, the eye-like spots at the sides rich orange-yellow. The plants of this species flowering here are not the very robust-growing kind, but, as in plants noted last week, they are by

comparison weak; yet they flower more freely and produce blooms equally as large and as highly coloured as the stronger type. W. H. G.

TREES AND SHRUBS.

W. GOLDRING.

CEANOTHUSES.

THESE plants do not, I think, receive the attention that their merits deserve, as they are easily grown and their beautiful racemes of blue flowers are borne with great freedom. They are nearly hardy; in fact, against an east wall at Chiswick they have, with a slight protection, withstood the severe winters we have lately experienced, and in the summer months they well repay any little trouble that may be taken with them in the winter in the way of protecting with mats, Fern, &c. There is no necessity to prune them until they grow too far away from the wall, in which case they may be, after all danger of frost is over, cut back close, when they will again break out fresh on all sides. We prefer, however, to leave them alone, thinning out only the small and useless wood, thus enabling the stronger shoots to produce more flowers. In the case of those which are planted out during the summer months, we find the best plan is to treat them like Fuchsias. Towards the end of March or beginning of April they may be stood in an open position so as to thoroughly harden them. When the time comes for planting out, say the first week in May, they may be taken out of the pots and planted, taking care that they have a good supply of water during the summer months. If attended to in this way they will, during the months of August and September, give a rich display of flowers, which will continue in full beauty until frost cuts them off. On the approach of frost the plants may be lifted and cut hard back and again put into pots and placed in a position safe from frosts. They will not require much water during the winter months, but as soon as they begin to break fresh they must have plenty of moisture. In due course they will be again ready to take their place in the flower garden. They may be treated in this way year after year, and by keeping them hard pruned both at the roots and the tops they will not grow to an ungainly size.

The following are a few of the best varieties, all of which have originated on the Continent and all are hybrids of *C. azureus*: *Sceptre d'Azur*, a vigorous grower, with large leaves and long racemes of blue flowers; *Gloire de Versailles*, one of the best, similar to the foregoing, and a truly beautiful variety; *Gloire de Vaite*, the dwarfest and best of all the *Ceanothuses*, the leaves small and the blue flowers produced in great profusion; *Azur* is similar to the last, but more compact in growth, the flowers bright blue; *Le Celestial*, a variety of strong growth, the racemes of bright blue flowers short and borne freely; and *Blue Celeste*, a plant of dwarf growth, the flowers very pale blue. *Marie Lemoine* and *Le Géant* are two varieties with pinkish white flowers, and which look well when planted along with those with blue flowers. T. W.

Rhododendron cinnabarinum.—The class of *Rhododendrons* represented by this species cannot be compared, as far as the showiness of their flowers is concerned, with many other kinds, yet the wide difference between their flowers and those of most other *Rhododendrons* makes them worthy of note. The flowers in the largest form are bell-shaped, about 2 inches long, and 1 inch in diameter, of a rather thick waxy texture, and borne in terminal clusters. Their colour is orange-red, generally somewhat paler towards the edges of the petals. The individual blooms greatly resemble those of that pretty Australian genus of plants, the *Blandfordias*; indeed, on one of these *Rhododendrons* the name of *blanfordiaeflorum* has been bestowed, but as usually met with it seems to differ little, if at all, from *cinnabarinum*. These *Rhododendrons* will survive most winters around London, but they usually flower best when treated as greenhouse plants, and planted out in a peaty border. Another of this class

is *R. retusum*, with small dark green Myrtle-like foliage, which when young is prettily tinged with red. The small tubular-shaped flowers are borne in clusters, and their colour, a sort of glowing orange-red, renders them very conspicuous. Both in shape, size, and tint, the blooms of this remind one of the scarce *Fuchsia triphylla*. This last-named *Rhododendron* (*R. retusum*) is by no means new, yet it is a very uncommon kind. Between this and *R. javanicum*, Messrs. Rollisson raised *R. Prince of Wales*, and more recently *R. Daviesi* has been obtained from the same cross.—T.

The Jerusalem Sage (*Phlomis frutescens*). Though classed as a shrub, this is by no means so woody a texture as most of them, yet it forms rather a conspicuous feature, owing to its being distinct from any other shrub and the blossoms being showy. The rugose leaves are of a peculiar hoary character, and the flowers, which are borne in whorls on the points of the shoots, are of a distinct bronzy yellow colour. The Jerusalem Sage will flourish where the soil is dry; indeed, in such spots it forms a more lasting shrub than in a free and moist position, where it at first grows rapidly, but after a few years commences to decay. The Jerusalem Sage is also noteworthy from its being one of the very few plants belonging to the Order Labiate that can be by any means classed as hardy shrubs.—T.

Eccentric Laburnums.—This is a correct designation to apply to some *Laburnums* in Mr. C. Noble's nursery at Summingdale. As is usual the pale purple *Cytisus purpureus* was grafted on to the stems of the common *Cytisus Laburnum*. Since then they have grown into good and vigorous young trees, and on some of the branches can be seen the tufted growth of *C. Adami* looking like a parasite feeding on the life blood of a different organism. But there is something more: from out of *C. purpureus* have also grown shoots of the common *Laburnum* bearing its long yellow racemes, and so the flowers of three distinct species can be seen on the trees at one time. The curious fact that by grafting *C. purpureus* on to *C. Laburnum*, *C. Adami* is produced, is now an old tale, but there are no doubt many readers of THE GARDEN who are unacquainted with this curious circumstance, and might desire to see it for themselves. The late Mr. C. Darwin alludes to the production of *C. Adami* in his "Origin of Species."—R. D.

Trees grown as bushes.—There is nothing finer for a small lawn or for groups on a large lawn. Among the best for this purpose are the Lindens, especially our common Basswood; the Catalpas, Tulip tree, Beeches and Birches; and among fruit trees the Cherries. I have on my lawns many specimens of Catalpa that are invaluable. They do not exceed 10 feet in height and are in some cases as many feet through, and are covered not only with rich foliage, but in the season with flowers. Most of the *Magnolias* do better cut in this form. The Linden furnishes much larger leaves, and will blossom freely when old. I have cut them down when 3 inches to 5 inches in diameter, and in two years secured superb shrubs. From E. Y. Teas, at Dunreith, I received some golden-leaved and purple-leaved Catalpas of his own cross-breeding. These are beautiful during the summer grown as shrubs. There are many people who long to grow trees, but have no room for large subjects. Let them grow any old favourite as a bush, and they will enjoy it.—REV. E. P. POWELL, in *Gardener's Monthly*.

The purple-leaved Barberry. In a recent number a correspondent, "T." calls attention to the merits of the above as one of the most striking for forming purple masses in the spring. He also says truly that the more fully exposed to the sun the more dense and brilliant the colouring. To prevent disappointment with this charming plant, I would add that the poorer the soil and drier the site the deeper the purple of the leaves. So much, in fact, is this variety dependent on site or soil, that it will lose most of its purple colouring by being planted in rich soil in a shady place. "T." names a companion plant to set off the purple-leaved Barberry to greater advantage, viz., the golden-leaved *Spiraea opulifolia*. This is good, as

is the less common golden-leaved *Syringa*, which matches the Barberry better in height. More effective, however, than either for contrast is the Silver Maple (*Acer Negundo variegata*). The latter also forms grand masses contrasted with the purple Filbert and the broad and darkest-leaved variety of the purple Beech. The latter is a most accommodating plant, and may with a little attention be cut and kept down to any height in the shrubbery desired. When this fact is more generally recognised by landscape gardeners, the purple Beech is likely to be more largely employed as a background for *Laburnums*, white Lilacs, light or silver *Rhododendrons*, &c., while for telling masses of purple in the fore or middle rank of shrubberies there are few plants equal to purple Filberts in the spring or summer months. HORTIC.

The Cockspar Thorn. Among the Thorns now in bloom, that known as the Cockspar Thorn (*Crataegus Crus-galli*) is the finest, and even if it flowered with the Hawthorn it would be conspicuous, as its broad shining foliage of a bright, cheerful green makes it so different from other Thorns. The flowers are not so numerous as those of the Hawthorn, but they have a more elegant appearance on the tree, and decidedly possess a more agreeable fragrance. Though not an uncommon tree, the Cockspar Thorn is not one of the stock-in-trade trees of the ordinary planter, and therefore large specimens of it are not frequently met with. Considering the beauty of this Thorn in autumn, too, when its leaves die off a brilliant colour, it is not one deserving neglect. There are several distinct varieties of it that are very valuable in ornamental planting. W. G.

The Californian Azalea.—The charming *Azalea occidentalis* perhaps receives more attention and is more admired than the numberless varieties of hardy Azaleas that flower in the American shrub ground at Kew. When all the others are out of flower, or on the wane, this Californian form stands out in full beauty, every bush of it being crowded with clusters of white and delightfully fragrant flowers, the contrast of which with the fresh and green foliage is most striking. A large bush of *A. occidentalis* is now in full bloom, attracting the attention of every visitor who comes to see the fading beauty only of the bright-coloured Azaleas. This Californian *Azalea* possesses a value which can scarcely be overrated, as it may be the means of producing a new race of hardy Azaleas, which may prolong the too fleeting beauty of the earlier flowering sorts. Already, we believe, the hybridist has been at work upon it, but there seems at present to be no race of hybrids that combine the high colours of the early kinds and the late flowering of *A. occidentalis*. W. G.

The Tamarisk in bloom.—This is a common object by the seaside, but it is rarely seen inland, though it will thrive as well as on the coast. The Tamarisk is frequently seen clipped and trimmed in to form hedges or screens, but when allowed to assume its natural character it forms a handsome specimen, of a very graceful habit, and just now an additional charm is furnished by the profusion of its pretty pink blossoms. These flowers are borne in small crowded spikes, and are thickly arranged on the upper portion of the long, wand-like shoots, and at a very little distance it is difficult to tell the flowers from the leaves except in colour. The Tamarisk will thrive in any soil, provided it is not too dry; indeed, it is a very pleasing object when in close proximity to water, though a very moist spot is not essential to its well-doing, the only condition to be observed in this respect being that it does not get parched up. Another commendable point about this Tamarisk is the fact that it can be readily propagated, for it is by no means necessary to put in small cuttings, as good sized branches will root if stuck in the ground.—T.

The Nine Bark. as *Spiraea opulifolia* is called in North America, is an invaluable hardy shrub, and one that everybody should plant who seeks only the best among the numberless shrubs to be found enumerated in nursery catalogues. It possesses all the qualities of a first-rate hardy shrub. It is

thoroughly hardy, grows anywhere, and where it thrives best makes a large handsome bush 6 feet or more high and twice as much through, and with its long slender shoots feathering the ground on all sides. For the past fortnight it has been in full bloom, every luxuriant bush being covered with myriads of small white flower clusters, which, being borne on slender twigs, are charming material for flower vases. It is useless to put this *Spiraea* in a dry, hungry soil and expect it to thrive. What it likes is partial shade, such as that afforded by a thinly planted shrubbery and a good and moist soil. Under such conditions it will grow rapidly, and will rival in effect such familiar old shrubs as the Guelder Rose and Mock Orange. The golden-leaved variety of the Nine Bark is even more valuable than the original, for it excels all other golden-leaved deciduous shrubs, keeping its bright sheen of golden leafage throughout the year, and is especially bright when first unfolded in May. By planting this golden *Spiraea* and the claret-leaved *Prunus Pissardi* together a fine effect may be produced.—W. G.

Erica cinerea.—This bright little Heath is again in full bloom, brightening many a rock garden with myriads of tiny flowers of a vivid

The Lily of the Valley Tree (*Andromeda floribunda*). Engraved for THE GARDEN from a photograph.

magenta. This is the colour of the common sort, but there are others that are darker and lighter, and some very much richer in tint. For instance, one sort called *coccinea* is of a glowing crimson-red, and is the finest coloured of all hardy Heaths. Another called *superba* in nurseries is likewise brighter than the type, while a third, called *pallida*, is of a pale purple, and *atropurpurea* of a deep purple. All these, if planted in prominent parts of a boldly planted rock garden, would make a bright show at this season for a fortnight or longer. The proper place to plant this and other Heaths is on a flat, exposed ledge where there is plenty of soil—if peaty so much the better—or at the foot of the rocks, but always in spots open to rain and sun. The smaller growing Heaths are often left out of lists of plants for the rock garden, though they are very suitable for it, and what plant gives a brighter effect in winter than *Erica carnea*? Though heatheries and American plant gardens are not made now-a-days a distinctive feature in gardens, the hardy Heaths should not be neglected.—W. G.

The Pyracantha in bloom.—The great profusion of brightly coloured berries borne by this Thorn serves to render it a conspicuous object during the winter months, and though its prominent features at that season are fully recognised,

little attention is paid to its blossoms, which are just now at their best. A specimen of it here is now quite a mass of white flowers, arranged in large, closely packed heads, and though individually small, yet from their numbers they make a fine display. As the blooming season of this Thorn occurs, too, when many of the others are on the wane, it is thus rendered additionally valuable. So profusely are the flowers produced, that I have seen small plants not more than a foot high quite a mass of white, but they had been struck from cuttings, and, therefore, flowered more freely in a young state than seedlings would have done.—H. P.

LILY OF THE VALLEY TREE.

(*ANDROMEDA FLORIBUNDA*.)

ONE of the best of dwarf shrubs, looking neat and well furnished throughout the year. The flower-buds are formed and considerably developed in the late autumn, so that the little shrub looks throughout the winter as if about to burst into flower; the flowers expand towards the end of March, and remain in beauty through-

out April. It is an excellent shrub for a rock garden. The single sprays are valuable for cutting, lasting long in water and looking well alone, or with almost any flower. J.

Golden-leaved Acacia.—Among trees remarkable for the yellow hue of their foliage at this season the golden-leaved variety of the common False Acacia is one of the best, for it is free and vigorous in growth and retains the colour of its leaves well. Unlike many plants, the leaves of this do not become green as the season advances, neither are they burnt up by the sun. Notwithstanding that the list of golden-leaved trees is somewhat extensive, many of them for some reason or other are not so valuable as this Acacia. In passing, mention may well be made of the great freedom with which these Acacias are blooming this season, and as they bloom after the bulk of flowering trees are past their best, they are additionally welcome.—T.

Magnolia tripetala.—Several of the Magnolias have very large and handsome foliage, but that with the largest leaves of all (*M. macrophylla*) is very particular in its requirements, and is seldom seen doing well. *M. tripetala*, on the other hand, is of a very vigorous constitution, and should be

made a note of where large-leaved trees are needed. It forms a free-growing tree of a somewhat open habit, the branches being furnished principally towards their extremities with magnificent foliage, which imparts to a large specimen a grand and imposing appearance. The flowers, which are large and of a whitish tint, are now very conspicuous by reason of their being borne on the tips of the shoots and surrounded by a ray-like whorl of the massive foliage. This *Magnolia* is a native of North America, and is also known as *M. umbrella*.—T.

GARDEN IVIES.

To say the Ivy is a neglected plant may to many appear incorrect, but those well versed in gardening hold a different opinion. There are perhaps few enthusiastic admirers of the plant, but that is no reason why it should not be grown in greater variety, and in a way to develop its true character. We have plenty of Ivies, but the selection is restricted to one or two kinds, and though we may occasionally find in some old-fashioned garden a wall or knoll clothed with luxuriant and glossy growth, yet it is the rule to place the plants under conditions least of all favourable to proper development. There is, unfortunately for the Ivy, an idea that it will live and thrive anywhere, but, though certainly hard to kill, it has its peculiarities, and these must be studied to ensure success. In the Royal Horticultural Society's gardens at Chiswick a collection is grown, and it is interesting to note the great variety in the form of the leafage and the habit of the various kinds. It is time a thorough trial was made of Ivies, as the nomenclature is at present almost hopelessly confused, and nothing but a careful revision and comparison will set matters on a proper footing. As regards this important point we have at present nothing more to say, as it is a subject that requires delicate handling, but we hope that something will be done at Chiswick to bring about order. As previously mentioned, the Ivy will not grow anywhere, and from experience it has been found that there are certain positions fatal to the welfare of the plants. On a hot wall, with full exposure to the sun, the Ivy never displays its splendid capabilities, and, again, in a starving dry soil it is equally unhappy. It is through being planted in such positions as these that it has, to a certain extent, fallen into disrepute, and earned the undesirable character of being slow in growth, straggling, and displaying more bare stems than leaves. To ensure a leafy, luxuriant growth, it is essential to provide a moderately shady position and moist, substantial soil; also, if possible, give the tender variegated varieties a corner where they will not be exposed to the full force of cutting east winds. We have seen the common Ivy of the hedgerow almost shrivelled up through this cause, but with genial weather the plants have generally quickly recovered. When treated as advised, it is surprising what rapid growth the different varieties make, and the colours of the variegated kinds are brighter by reason of the vigorous health of the plants. A collection of Ivies costs a comparatively small sum, and it will be always a source of interest, as the several forms differ widely in character. It is unnecessary to enter into detail respecting the cultivation, propagation, &c., except that we may mention with advantage that cuttings of the delicate variegated sorts should be struck in pots placed in a cold frame, as if dibbled in a border out of doors many of them fail to root. The collection at Chiswick was planted about twelve months ago, and it is astonishing the progress some of the varieties have made, especially where the plants are situated in shady, moist positions, as we mentioned was in accordance with their requirements. We have selected a few, of which the following are the best: *Emeritus grandis*, an excellent green-leaved variety, neat habit and foliage, and a quick grower. *Emerald Gem* is king of the green-leaved section, the growth dense, and the habit remarkably robust. It grows rapidly, and soon covers a comparatively large space; one of the best for the garden we know. *Lobata major* is another variety of this class, neat in habit, the leaves dark green with

white nerves. Minor is a pleasing neat-growing Ivy, not very robust, but clings close to the wall. To those forming a collection it is invaluable for its distinctness. *Palmata aurea* is a variety that requires the association of green-coloured foliage to bring out the bright yellow of its leaves, which are palmate and of moderate size. *Angularis aurea* is a dense grower, the majority of the shallow-lobed leaves coloured with yellow; it is a useful variety. *Succinata* is distinct, and its leaves are all pure yellow, but it lacks robustness, though it might be highly prized by an Ivy fancier. *Spectabilis aurea* makes a free growth when suitably placed; but, like most of the variegated kinds, it will not thrive everywhere. *Elegantissima marginata rubra* is a neat, pretty Ivy, but will not do in hot exposed spots; its leaves are green margined with silvery white. Why it is called *rubra* is not apparent, as there is not a trace of red on the leafage, but perhaps this colour may be developed later on. *E. m. grandis* is of spreading habit, the leaves medium-sized and of a similar colour to the last mentioned. The type is a beautiful variety when properly treated, the leaves almost triangular, small, and broadly margined with creamy white. *Himalaica* makes a free, picturesque growth, and clings close to the wall; the leaves are small, ovate, green, with dull white nerves; a useful kind. *Caenwoodiana* is distinct, and a thoroughly serviceable Ivy for a prominent position; it is neat, fairly vigorous, and has pleasing green leafage, the middle finger-like lobe giving it a characteristic appearance. *Sagittifolia* is a good garden Ivy, though its name is misleading, as the long, green, small-lobed leaves are more hastate than sagittate. *Rhomboides ovata* we have seen do well in some places, but it is not one of the best, the growth being too stiff and formal; the leaves are ovate, leathery, and deep green. *Dentata*, as labelled at Chiswick, presents a contrast to any that we have mentioned. It needs plenty of space to develop its abundance of large cordate leaves, which change from yellowish to deep green. It would do to plant against a wall that requires covering, but not for a prominent position, as it is not sufficiently refined in appearance. *Poetica* is a useful Ivy for a shady wall; so also is *contracta*. The variegated variety of the Irish Ivy and *Ragneriana* are too well known to need further mention, as they are among the commonest. Such vigorous growers as these are more suited for covering fences than the small-leaved Ivies, which may be used for clothing tree stumps, rockeries, and rustic arbours with the best results.

E. C.

The Tamarisks are among the flowering shrubs of the week, and they have an extremely pretty effect with their long, wand-like shoots clothed with feathery foliage and plumes of pale pink bloom. Though usually planted most plentifully in seaside districts, they grow and flower luxuriantly in inland gardens, and are capital shrubs for planting in dry, poor spots where stronger growing shrubs would fail. They are so much unlike other hardy shrubs, that for the sake of variety they deserve attention. There are several kinds, but the most readily obtainable in nurseries is *Tamarix gallica*. On the light soil at Kew all the Tamarisks thrive perfectly, and a dry bank in the arboretum is beautifully clothed with them, some being now in full bloom.—W. G.

Japanese Lilac (*Syringa japonica*).—Some cut blooms of this new hardy shrub exhibited by Messrs. Veitch at South Kensington on Tuesday showed admirably what a valuable introduction it is. There is a family likeness among all the other species of *Syringa*, but this one is so different from the rest and so much resembles some of the Privets (*Ligustrum*), that it was and still is known as *Ligustrum amurense*. Since, however, the nature of its fruit has become known to botanists, it is found to be a true species of *Syringa*. In foliage it strongly resembles that of the Himalayan Lilac (*S. Emodi*), being quite as large and of similar colour. The myriads of tiny creamy white flowers are borne in paneled clusters at the tips of the shoots. At first they are quite white, but afterwards turn creamy. The perfume of the flowers is similar to that of the

Privet, but less powerful. It is apparently quite hardy, and if it can be grown in any position or soil as other *Lilacs* its value is increased.—W. G.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL.

HARDY JUNE flowers, Orchids, and various other miscellaneous plants made the meeting on Tuesday last one of the most interesting that has been held this year. It was larger and displayed greater variety than the previous one, the exhibits comprising a number of very rare subjects, a few, notably the magnificent specimen *Cattleya gigas*, from Mr. G. Nevile Wyatt, Cheltenham, evincing high cultural skill.

First-class certificates were awarded as follows:—

HEUCHERA SANGUINEA.—This is now fairly well known, and will quickly become a popular garden plant by reason of its bright appearance. It is quite hardy, the habit very compact, and the effective reddish scarlet flowers produced freely in neat spikes. It comes from Mexico, and is well adapted either for the border or rockery. Shown by Mr. T. S. Ware, Tottenham.

ROSE CLEOPATRA.—A fine addition to the pedigree Tea Roses. Mr. H. Bennett, of Shepperton, showed several flowers of large size, beautiful form, and delicate fragrance; the petals are exquisitely arranged and both broad and firm, the colour being of a delicate tint of salmon-pink, deepening towards the centre of the flower; the petals are also edged with the same hue.

ROSE LADY ALICE. A sport from Lady Mary Fitzwilliam, and of similar size and form, but different in colour, being almost white, with a pinky centre. If it keeps its character it will prove an acquisition. Exhibited by Messrs. Paul and Son, of Cheshunt.

SYRINGA JAPONICA.—A beautiful free-flowering shrub, reminding one of the *Ligustrum* or Privet. It bears a profusion of large, dense clusters of creamy white flowers, which have a foam-like appearance and powerful fragrance. From Messrs. J. Veitch and Sons, Chelsea.

GAILLARDIA VIVIAN GREY.—A bold variety, with large flowers, having broad, bright yellow ray florets and centre. It will make a useful garden plant by reason of its effective colouring. Exhibited by Messrs. Kelway and Sons, Langport, Somerset.

PEONY GLORY OF SOMERSET.—This is a very large-flowered variety, but is neither coarse nor gaudy. The colour is of a telling shade of pink, and the form is good. Exhibited by Messrs. Kelway.

DELPHINIUMS BRITANNIA AND CHAMONT.—Two fine varieties. The former bears a long, somewhat loose, symmetrical spike of double flowers, the outside petals bright purple, the inside creamy white. The last-mentioned has a dense spike, fully 18 inches long, of bright metallic-blue and reddish bronze flowers. From Messrs. Kelway.

CHRYSANTHEMUM LEUCANTHEMUM SEMI-DUPLEX.—Flowers pure white, slightly double, and pretty. Exhibited by Messrs. Saltmarsh and Son, Chelmsford.

CYPRIPEDIUM SUPERCILIARE.—A well-grown plant of this was shown bearing six flowers. It reminds one of *C. superbiens*, the foliage being handsome, broad, and distinctly tessellated. The flowers are of bold form, the lip reddish brown, and the petals dull coloured, with conspicuous deep crimson warts at the margin; the dorsal sepal is white, with green and crimson veins. Exhibited by Sir Trevor Lawrence, Bart., M.P., Dorking.

CATTELYA LABIATA LEUCOPHEA.—A very distinct and interesting variety. The flower is of medium size, with the sepals and petals very pale rose, approaching to white; the lip is of a peculiar shade of lilac, the base being white and the throat striped with yellow; the edge delicately crimped. Shown by Mr. F. G. Tautz, Shepherd's Bush.

AERIDES EXPANSUM LEONIE.—An attractive and

rare variety, bearing a similarity both to *A. falcatum* and *A. Houlettianum*. A plant was shown having a pendent spike of brightly coloured flowers, which are not set so closely as in many of the *Aerides*. The sepals and petals are white, tinged and tipped with rosy red; the middle lobe of the lip is well developed and suffused and spotted with rose-crimson; the lateral lobes being pure white with spots or stripes of the same bright hue. It is a variety that should be in every choice collection. Shown by Mr. F. G. Tautz.

ORCHIDS formed the most interesting feature. Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, exhibited a fine collection, containing many varieties, and the whole of the plants showed careful cultivation. Among the most important were *Bolbophyllum barbigerum*, a botanical curiosity, the finely hinged lip having a prominent brush of reddish brown hairs, which cause it to oscillate at the slightest movement; *Cattleya gigas Sanderiana*, a splendid variety; the lip fully 3 inches across, and of an intense crimson-purple; the whole flower is richly coloured. A good specimen of *Phalaenopsis Marie* was exhibited; this is allied to *P. sumatrana*; the flowers being borne in a pendent raceme, with the sepals and petals white, transversely barred with rich brown; the lip is of a beautiful shade of magenta, the margin white. *Aerides Godefroye* is a fine form; the flowers are sweet-scented, and produced in a pendent raceme; the lip is rosy pink and the sepals and petals are spotted with the same hue. The rare *Galeandra nivalis* was also shown. This has reflexed deep brown sepals and petals and a broad lip, white flushed with dull violet. *Lycaste Deppii punctatissima*, a beautifully spotted variety, was in the collection, also a white-flowered unnamed species of *Aerides*, the flowers pure waxy white. *Cypripedium caudatum* was represented by a sturdy plant bearing several well-coloured flowers. We frequently find this grown in the East Indian house, but this specimen had been grown with the *Odontoglossums*, and its healthy condition showed that the treatment suited its requirements. *Cypripedium Curtisi* is a fine Lady's Slipper, the lip large, dull brownish purple; the petals are spotted and flushed with crimson, the dorsal sepal being veined and suffused with green, the margin white. *Cattleya Schilleriana* was exhibited in fine condition; this is peculiarly rich in colouring, the deep brownish sepals and petals contrasting effectively with the brightly coloured lip, which is shaded and striped with deep crimson-pink.

The *Cattleya gigas* from Mr. Simeoe, gardener to Mr. G. Nevile Wyatt, Lake House, Cheltenham, was a model specimen, the leafage robust, and the plant carrying on four sturdy spikes upwards of twenty-six well-coloured and boldly-formed flowers; the lip measures about 3 inches across and is of a bright purplish crimson, with two eye-like blotches at the base. A bronze medal was awarded.

From Mr. A. J. Hollington, Enfield, came *Odontoglossum vexillarium Hollingtoni*, and a variety of this Orchid named Pagei was also shown by Messrs. H. Page and Son, Teddington. Mr. F. G. Tautz, Studley House, Shepherd's Bush, exhibited the beautiful *Phalaenopsis Marie*, also *Odontoglossum vexillarium striatum*, a well-flowered variety, the base of the lip of a rich crimson with radiating stripes. A cultural commendation was awarded to Mr. J. Ridout, gardener to Mr. T. B. Haywood, Woodhatch Lodge, Reigate, for *Odontoglossum vexillarium Regina*, the specimen bearing two racemes, the lip being large, pink, and striped with rich crimson at the base. Mr. D. East, gardener to Mr. F. Wigan, Clare Lawn, Sheen, showed *Dendrobium polyphlebium*, and also a variety of *O. Alexandra*, with large white flowers; the crest deep yellow.

HARDY FLOWERS made a fine display of colour. Mr. T. S. Ware, Tottenham, exhibited a large group, comprising many interesting plants. The most noticeable were: *Delphinium Héricart de Thury*, a bright bluish purple variety; *Arum eructum*—this is remarkable for the immense size of the spathe, which is reddish and coated with hairs; *Campanula grandis major*, a deep violet-purple variety, the flowers large and produced in dense spikes; *Inula*

glandulosa, a fine variety, the flower-heads measuring fully 5 inches, and of a rich orange colour; *Helianthus occidentalis*, an early-flowering and dwarf-growing perennial Sunflower; *Lilium pomponium*, recently reintroduced from the Southern Alps, the foliage narrow, and the flowers of a brilliant scarlet colour; and the white form of the common Maragon Lily. A silver medal was awarded. Messrs. Paul and Son, Cheshunt, also staged a group, comprising Peonies and other flowers in season. A silver medal was awarded. Messrs. Kelway and Son, Somerset, were awarded a bronze medal for a collection of Delphiniums, Gaillardias, Peonies, and Iris. Amongst the former, Apollon, deep blue, and Cherub, light metallic blue and pink, were conspicuous. Messrs. Barr and Son, Covent Garden, received a like award for their group of hardy flowers.

The Poppies raised and shown by the Rev. W. Wilks, Shirley Vicarage, Croydon, displayed an interesting range of colouring, comprising delicate pinks, pure whites, and rich scarlets. All were varieties of the common English field Poppy. Mr. T. Laxton, Bedford, showed a new Sweet Pea, named Invincible Blue, the colour being a fine blue. Carnations were sent by Mr. H. B. May, Dyson's Lane, Edmonton, the whole of the plants well flowered. The varieties included Miss Joliffe, one of the best; Dr. Raymond, similar in colour and fragrance to the old crimson Glove; and Belle Halliday, light yellow. Mr. J. Douglas, Great Gearies, Ilford, contributed Picotee Almira, a yellow ground of good form, the petals coloured here and there with light red; and P. Agnes Chambers, also a yellow ground, the flower full, lightly edged with pale terra-cotta colour.

From Mr. Henry Bennett, Shepperton, came the pedigree Tea Roses Princess Beatrice and William Francis Bennett. The first is well known, and the latter is a deep carmine, beautiful in the bud, but when fully expanded shows the centre. Mr. R. Dean sent *Chrysanthemum coronarium* Sunbeam, bright yellow, and varieties of *Dianthus plumarius*; and from Mr. O. Hodges, Lachine, Chislehurst, came Sweet Pea Terra Cotta; *Begonia Gaston Wirix*, semi-double pink and yellow; and B. Gilbert, a rich scarlet double variety.

Messrs. J. Veitch and Sons staged *Styrax japonica*, a free-flowering, elegant, and pretty tree with white blossoms; and *Andromeda speciosa pulverulenta*, which bears dense spikes of pretty white, bell-shaped flowers. Mr. C. Noble, Bagshot, showed *Acacia Decaisneana*, a pink variety of the False *Acacia* (*Robinia Pseudacacia*); the flowers are borne in large pendent racemes. Mr. Gordon, Twickenham, exhibited a new Japanese Maple, *Calceolaria Cloth of Gold* came from Mr. W. Rapley, Bedford Hill House, Balham; the flowers are large and of a bright yellow colour.

Fruit committee. Fruit was fairly plentiful. Mr. Charles Turner, Slough, exhibited Turner's Green Flesh Melon, a large fruited variety; and from Mr. Goodacre came Lockington Hall Muscat and Rockferry Hamburgh Grapes, the first a white variety, and the other black, both being of good appearance. Mr. Clarke, of Twickenham, sent a basket of Pauline Strawberry, a variety with large, highly-coloured fruit; and a collection of Apples in an excellent state of preservation, considering the season, was exhibited by Mr. John Watkins, Pomona Farm, Withington, Hereford. The best of the varieties were Moss's Incomparable, Striped Beaufin, Dumelow's Seedling, Winter Greening, Hambleton Deux Ans, Norfolk Beaufin, and Rymer.

In competition for the prizes offered by Messrs. Carter and Co. for Melon Glenheim Orange, Mr. T. Lockie, the Gardens, Oakley Court, Windsor, was first with a fine fruit; Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, being second; and Mr. C. J. Waite, Glenhurst Gardens, Esher, third. The same firm also offered prizes for a brace of Cucumbers, Messrs. T. Lockie and C. J. Waite being first and second respectively, and Mr. G. Collins, gardener to Mr. J. A. Ross, Wandsworth Common, third. Special prizes were also offered by Messrs. Sutton and Sons, of Reading for a brace of Melons, Mr. J. H. Goodacre,

Elvaston Castle Gardens, Derby, coming first with fine fruits of Hero of Lockinge; Messrs. C. J. Waite and T. Lockie were second and third respectively. For the special prizes offered by Messrs. Webb and Son for Melons, the prize-takers were Messrs. J. H. Goodacre and T. Lockie in the order named.

Special Meeting.

A special meeting of the Royal Horticultural Society was held on Tuesday last at South Kensington for the purpose of announcing to the Fellows the real position of the society, and to gain their opinion as to what should be done for its future welfare. There was a good attendance, including many of the leading horticulturists, and throughout there was manifested a keen interest in the society and a desire to place it upon a sound basis, so that it may become a real power in the furtherance of practical and scientific horticulture in this country. The chair was taken by Sir Trevor Lawrence, Bart., who, in the course of his remarks, mentioned that the state of affairs was very much as it was last spring, and the uncertainty as to the future of the society was having a prejudicial effect upon it, several old Fellows having ceased to become members and no new ones joining. The Royal Commissioners of 1851 offered a site, but it was inadequate, and the council have done all in their power to obtain one, but their efforts have failed. Moreover, the expenses were still going on, and not decreasing, so that under the present condition of things the society would soon be in debt. Under the most favourable circumstances there will be at the end of the year a deficit approaching £1000, this being due in a great measure to the failure of the Liverpool show. The chairman felt sure that if the society were to put forth a definite and practical scheme that it would be supported. The council propose to take steps for the future housing of the society, and, with a view to economising, to carry on the operations for a time at Chiswick after the end of the year. The opinion that prevailed was in accordance with this proposal, but that large shows and the meetings should be held near the city, Chiswick not being sufficiently central. It was thought that by so doing the sphere of usefulness would be extended, and the society become far more national in its character than it is at present. It was proposed and seconded that steps be taken immediately to secure accommodation for the society at the close of the year, either permanent or temporary, in some central situation in or not far from the city.

Gardeners' Orphan Fund.—The first general meeting of the supporters of this fund will be held in the conservatory of the Royal Horticultural Society, South Kensington, on Tuesday, July 12, at 3 p.m., to receive and adopt the report of the provisional committee as a basis upon which to establish the Gardeners' Orphan Fund, to elect officers, executive committee, &c. It is hoped that all sympathisers with the movement will make it convenient to attend. Mr. A. F. Barron is the honorary secretary.

Gardeners' Royal Benevolent Institution.

The annual dinner of this institution took place on Wednesday evening at the Albion Hotel, Aldersgate Street, E.C. Baron Ferdinand de Rothschild, M.P., presided, and a very large company was present, including many of the leading horticulturists. The chairman proposed the toast of the evening, and in a careful and able speech reviewed the past history of the institution, which originated as far back as 1839. After it had once established itself it made vigorous progress. He strongly advocated the claims of the institution, and appealed for a further increase in the funds to meet the need of those who seek for assistance, but which cannot be given until the subscriptions are increased. He felt sure that it might be supported even more liberally than it is by the gardeners themselves, and mentioned the resolution of the committee to increase the list of pensioners to 122 to fittingly mark this jubilee year of Her Majesty. Mr. Harry Veitch, the present treasurer, said that the first year £126 were obtained, the next year £200, and from that time the funds have steadily increased.

The annual subscriptions were highly satisfactory, and the secretary, Mr. E. Cutler, announced that over £1400 had been received that evening, £714 coming from the gardeners—a healthy sign for the continued prosperity of the institution.

THE RATING OF NURSERIES.

A PUBLIC meeting of nurserymen was held at the Horticultural Club on Wednesday last "to take into consideration the excessive rating of nurseries, and to agree on a combined course of action with a view to the reduction of assessments." Mr. J. Wood-Ingram, of The Nurseries, Huntingdon, took the chair, and there was a good attendance. The secretary (Mr. Goodchild) read several letters received from nurserymen in various parts of the country, who pointed out the unfair rating of nurseries. One individual, writing from Middlesex, stated that for one place he paid £20 a year and was assessed at £15; for another he paid £15 and was assessed at about £70. The chairman pointed out that there was no satisfactory basis of assessment, and it was desirable that a case should be decided by the highest court, so as to obtain such a basis. He showed, by illustrations derived from his own experience, that the amount of assessment was determined in a haphazard manner. He moved the following resolution:—

That this meeting of nurserymen and market gardeners, representing the London and provincial trades, hereby protests against the excessive rating of nurseries and the absence of any basis on which the assessments are founded, and is of opinion that the matter is one which calls for combined action with a view to taking such steps as may be necessary for placing the assessments on a well defined basis; and pledges itself to do all in its power to effect this purpose.

Mr. Sharman (Carter and Co.) seconded the proposal, and said that for one house his firm paid £100 a year, and was rated at £200. The whole thing seemed crude and undefined. Mr. Bennett argued that the assessments must be based on the rentals. Nurserymen could remove their erections when they liked, and that proved that the erections were nothing but chattels, which could be removed in case of bankruptcy. He had long been engaged in assessment work, and had never known one single case in which the assessment of an agricultural holding was advanced unless the rent had been increased. He advised that everyone should refuse to pay on anything more than his rental.

Mr. Haines, Penge Nursery, stated that he had in hand an action against his parish for the return of £250 odd, which they had illegally taken from him. The discussion was continued by Mr. Horsman, of Inkley, near Bradford; Mr. Beer, of Worthing (who advocated the formation of a deputation to wait upon the Home Secretary with a view to the appointment of a commission); and Mr. Cobb, Forest Hill; and the resolution was then agreed to unanimously. Mr. George Bunyard, Maidstone, moved:—

That a committee be appointed to carry out the previous resolution.

Mr. Haines seconded, and it was agreed to. The following gentlemen consented to act, and were given power to add to their number:—Messrs. Sharman, Wood-Ingram, Haines, Beer, Pearson, Williams, Horsman, Bennett, and Bunyard. Mr. Chitty, Walthamstow, moved that a guarantee fund be raised. This was seconded by Mr. Lowe, Ex-bridge, and agreed to.

Royal Horticultural Society, Chiswick.—We learn that the Strawberry fête is fixed for Saturday, July 9.

We learn from *Nature* that Miss Oldfield has presented to the herbarium of the Royal Gardens, Kew, the botanical collections made in Australia by her late brother, Mr. Augustus Oldfield. The series of Eucalypts are especially good, as great pains were taken to obtain the characteristic forms of each species.

Names of plants.—*E. B.*—*Asimina triloba*.—*J. F.* 1. *Sempervivum arachnoideum*; 2. *Tussilago Farfara variegata*.—*J. Stapleton*.—1, 2, 3, 4, varieties of *Orchis maculata*; 5. *Iris pseudacorus*.—*F. M.*—Impossible to name varieties of Iris.

WOODS & FORESTS.

"YORKSHIREMAN."

THE GIANT ARBOR-VITE.

(THUJA GIGANTEA.)

THAT the climate of Britain is peculiarly well suited for the development of this stately, fast-growing tree is certainly beyond a doubt, for although introduced only thirty-five years, many specimens of 70 feet and upwards are to be met with. On this estate the annual rate of growth exceeds that of most other trees of which I have kept a record, twenty-four trees of this Thuja growing under ordinary conditions in the park having made an average annual growth of 22 inches; but even this is far surpassed by young trees of 8 feet or 10 feet growing in the home nursery. Unlike many of its American relatives—such as the Wellingtonia and Sequoia—this tree is never seen with a Carrot-shaped stem, but gradually tapering throughout, and terminating in a leading shoot that is as thin and pliable as a whip-handle. As an illustration of what is meant, we may say that the usual stem girth of a specimen 60 feet in height is 4 feet at a yard from the ground; whereas a tree of the Wellingtonia of similar height would in most instances be double that girth, and with a fast taper from base to tip. The branches are numerous, very irregularly arranged along the stem, and short in proportion to the tree's height, the branch diameter of a 50 feet high specimen standing alone being usually but 12 feet at the widest part. They are placed at right angles to the stem, or nearly so, very flexible, frondose, and with up-curved tips, and thickly covered with scale-like, finely-pointed leaves, which are of a bright glossy green on the upper side, and distinctly glaucous beneath. Usually the cones, which are fully half-an-inch long, and resembling those of the common American Arbor-vite, are produced in great abundance on the upper half of the tree, and when fully ripe impart, from their great quantity and tawny brown colour, a by no means uninteresting feature to the tree. Judging from several hundreds of this tree planted over the estate, I should say that a deep, sandy, but moist loam suits this tree best; but yet it is far from particular as regards choice of soil, for we have numerous grand, rapid-growing, well-furnished specimens on deep well-decayed vegetable matter, rough sandy soil, rocky debris, and in loam of a rather clayey nature.

Professor Macoun, of Ottawa, tells me that he has found this tree of largest size where growing in rather damp alluvial deposit; indeed, that it is almost unknown in the dry central plateau, but plentiful along the coast and lower parts of the rivers in its Canadian wilds. As to exposure, this Thuja is likewise to a great extent indifferent, although we must admit that even in our warm maritime county there is certainly a marked difference between trees growing in sheltered, sunny corners and such as are fully exposed to cold, keen-blowing winds, but even in the latter situation and when at a moderate elevation above sea level this tree does fairly well—better, indeed, than many other kinds that have been brought from the American coast. Even during the memorable Tay Bridge gale, when almost every tree suffered in some way or other, this Thuja remained unharmed, and I can safely say that during my ten years' sojourn at Penrhyn I have never seen a single specimen uprooted or a leader broken over by the wind. This latter is not to be wondered at, for I have more than once tied a knot on the leading shoot, so pliable and tough is the wood, and which, when released, springs back to its original position in a manner that is quite surprising.

The timber of this tree, as everyone must know who had the privilege to behold the huge logs and nicely dressed smaller boards in the Canadian court of the late Colonial Exhibition, is of excellent quality, and highly prized by our American cousins. It is of a desirable yellow colour, fine in the grain, easily worked, remarkably durable, and, what is especially valuable in any wood, light in proportion

to its bulk. It must be understood, however, that we are now referring to timber produced in Canada, for as few specimens of this tree in Britain have reached a greater age than five-and-thirty years, the timber cannot be said to have attained to anything like maturity. From a specimen preserved here, and which was grown on the estate, it appears little different either in colour or texture from that produced in its native country. The large butt of this tree referred to above, and which attracted a great amount of attention at the Colonial Exhibition, was no less than 21 feet in girth, and was taken from a tree 250 feet in height. Professor Macoun mentioned that this specimen might be considered as about the largest, but that, under favourable circumstances, the average dimensions reached by this stately, fast-growing tree are but little less.

In many instances the largest trees are hollow, and he likewise told me that it was not at all uncommon for several stems to issue from one crown, and that, like the Spruce Fir in this country, the outer branches of large specimens growing along the margins or open portions of the wood when they come in contact with the ground, take root and send up stout stems, thus imparting a curious appearance to such portions of the woodlands.

The north-west coast of the United States may be considered as the headquarters of this giant Arbor-vite, and where it may be seen of all sizes from 10 feet or 50 feet to about 250 feet in height, and with stems girthing from 12 feet to sometimes as much as fully 40 feet, these being clean, straight, and of gradual taper throughout. Not only for its timber, but bark as well, is this tree highly valued in its native country, this being converted into mats, ropes, clothing, and other articles of domestic economy. As the timber works readily and takes a good polish, it is much sought after by the American cabinetmaker, while most of the canoes made on Vancouver's Island are cut out of it, as also boats and ships; while for lasting qualities it surpasses most of the native timbers, for we were told that in repairing an old fort the only log found sound after twenty-one years' trial of those used for under-pinning was that of an Arbor-vite.

Some five years ago we planted experimentally a small piece of ground near sea level with fine healthy 4 feet high plants of Thuja gigantea. These were planted at 16 feet apart, and the intervening spaces filled up with Larch and several species of hardwood for removal at an early date. The soil being rather cold and damp, though artificially drained, was not well suited to the perfect development of this fast-growing tree, and, moreover, it was of a stiffish nature, in some places rapidly inclining to clay. To obviate the evil as much as possible the ground was well turned up at the time of planting, and the soil exposed for a short period to the ameliorating influences of a winter's frost. The plants have now become quite established and are growing rapidly; indeed, an examination of several specimens made to-day clearly shows that they will ultimately surpass both in height and stem bulk any of the other trees with which they are associated. It is evident from the narrow spread of the branches of this Thuja that it is eminently adapted for forest planting—at least that it will succeed better when grown thickly together than the majority of Conifers whose spread of branches is wide in proportion to their height. As it may be transplanted when of large size, this Thuja is of great value for filling up gaps in young plantations, and as its hardihood in this country is now quite an established fact, it bids fair to outrival many others for planting in even the coldest parts of the British Isles.

As a substitute for the Larch, in conjunction with the Corsican Pine and Douglas Fir, this giant Arbor-vite is well worthy of attention; indeed, it possesses qualities of which both these species are deficient, viz., in its being readily transplanted at all sizes up to 6 feet (want of this is the Corsican's greatest drawback); while its leading shoot never gets injured on rising above its neighbours, a fault to which we have found the Douglas Fir particu-

larly susceptible. The nursery management of this Thuja is also of the simplest description, it being very readily raised from seed, perfectly hardy in its younger stages, and at all times bushy, well rooted, and consequently sure-footed. It may, however, be well to say that ample space should at all times be allowed it whilst in the nursery borders, and oft transplanting, as with other trees, induces the formation of numerous rootlets; therefore, to have nice bushy specimens the two requisites alone are plenty of room and frequent removals. As an ornamental tree Thuja gigantea holds a high place, its compact, but easy contour, beautiful vivid green foliage, and well furnished appearance even when planted under what might be considered as disadvantageous circumstances rendering it a general favourite with the lover of hardy trees. Planted either singly or in masses of, say, five or seven together on the greensward and in close contiguity to clumps of the more still-growing Pines, it never fails to attract attention and produce the most pleasing effect. Again, as a single specimen for planting at irregular intervals around the margins of plantations that are visible from park drives and walks it is well suited, and quickly forms a neat tree of very pleasing appearance, and in such positions is of great value for lighting up our deciduous woodlands during the winter months. This handsome, fast-growing tree was sent to this country by Jeffrey in 1851. A. D. WEBSTER.

WOODS FOR GARDEN FRAMES.

THERE is probably no wood better suited for making frames than home-grown Elm. It is certainly somewhat heavy, but as extreme portability is not a great consideration, this is of little consequence. In any case the objection is overcome by building the frames so that they can easily be taken to pieces. Discretion, however, is necessary in selecting material, or disappointment is sure to follow. Young, tough, and imperfectly seasoned wood will be a source of continual trouble. A clear and well-matured butt of Elm for conversion into planks of from 1½ inches to 1¾ inches in thickness for good-sized frames is none too heavy. This should not be cut through and through so that the planks or boards come off at various widths and with wavy edges, but what is technically known as a "stock," i.e., a single thick plank of from 12 inches to 20 inches in thickness should be taken out of the centre of the tree. This is afterwards reduced to the 1½-inch or 1¾-inch boards or planks. By these means the best part of the tree is secured, and the edges of the planks square and free from sap. Approximately too they are in line with the grain. In Elm this is not so important as in some woods, but it is nevertheless a great advantage, as it makes the material less absorbent. As a proof of this, Oak cut across the grain is useless to cask-makers on account of its allowing the liquor to penetrate. The length of time these planks will take to season will, to a certain extent, depend upon circumstances. At first sight it may appear that, as the frames have to be constantly exposed, the use of seasoned wood will matter but little. This, however, is a mistake, as no frame can be considered complete until it has been thoroughly painted, and what the painting of imperfectly seasoned wood means, those who have had opportunities of observing will not be at a loss to determine. The actual method of construction is rather a question for the carpenter than for the yard manager or the gardener, it always being necessary that the joints should be made close to prevent the escape of heat; plunging and tonguing are probably the safest plans. In speaking of frames, of course, I refer to the frames proper, and not to the sashes or lights. The woodwork of these is generally made of the best red deal. As a small amount of twisting or warping is almost inevitable from the nature of Elm, especially when cut into small dimensions and unsupported, clean seasoned Oak is to be recommended in preference to it for the bars across the frame upon which the lights slide. Deal being more easily worked, there is a temptation to use it for this purpose instead of Oak, but when Oak is available it should always be chosen, as when selected with judgment it will last as long

as the remainder of the frame. A little thought will show that it is upon these bars that the great stress comes, and that constructing them of proper material is very important. D. J. YEO.

THE EXHAUSTION OF THE SOIL BY THE ROOTS OF TREES.

"T. B." directs attention to this in *THE GARDEN* (p. 517). While agreeing with him as to the evils of a starvation treatment for the roots of trees, I think this arises oftener for lack of timely thinning than from over-thick planting. There is but little risk of any serious scarcity of food during the earlier stages of the growth of trees and shrubs. Through these stages the soil is fresh, and mostly fairly well stored with plant-food. What the plants need most is shelter, warmth, quickening stimulus to enable them to utilise the food in the soil, rather than largish masses of food in bulk, set aside each for itself. It is thus that thickish planting fosters, not hinders, growth—provided always that overcrowding or crushing is avoided, and that prompt and timely thinning takes place before the competition for food among the roots becomes so severe, that the weakest must suffer severely, or go down in the severe struggle that must ensue over the survival of the fittest—that is, the strongest.

It is difficult, not to say impossible, to remedy the evil results of such destructive competition at any future period. True, when plants and roots are thinned out, those left will hasten to occupy the vacant places of those cleared away. But it is not always the best or most profitable plants or roots that survive. Very frequently it is very much the contrary, and no after treatment or subsequent thinning can recall the dead roots to life again. Even weakly or sickly ones are long in recovering to perfect health, and in not a few cases trees or plantations never recover their early crushings and starvings.

So obvious is all this, that some planters have been driven to find excuses for thick planting and slow thinning, on the ground that by using mixtures,

the evil of too many mouths for the food present in the soil is greatly mitigated, if not wholly cured. If it be true, and it is, that one man's meat is another man's poison, why should not the same law or truth hold good among the roots of trees of widely differing species and varieties? Hence they fail to see or admit what seems so obvious to "T. B.," "that the earth can no more sustain two plants where one requires all the nutriment present than it can feed two animals on a space only large enough for one." It may, or can, they reply, provided the two plants choose and indeed require, very different nutriment. And were not this the case to a very large extent, it would be quite impossible for the earth to carry half the crops that it does.

And in the case of trees and shrubs, &c., not only do the plants to a large extent feed on different foods, but each also feeds on a different plane—that is, a distinct depth from the surface. Hence the wisdom and profit of a mixed crop, especially in permanent plantations. Only thus can all the feeding properties of the soil be utilised to the best advantage and turned into the most profitable channels.

But none of this is meant to oppose "T. B.'s" protest against root-starving by over-crowding and under-feeding, but rather to show how trees subsist and grow at times under the most unfavourable conditions. One set may thrive on the other's leavings, and the wide-running, deep-boring roots are always reaching and utilising fresh fields of food further afield or deeper down.

How far a food-famine at the roots quickens their extension has never yet been clearly shown, but that root-hunger stimulates root-growth can hardly be doubted, as it is mostly found in practice that the poorer the soil the further the roots run, and the more widely and minutely they ramify; and no practical man needs to have explained to him the important bearing of this latter feature of root-structure on their collecting and feeding properties.

HORTUS.

Garden seats and trellises.—This is the most suitable time for securing the small Oak branches that are used for garden seats and trellises. Where a felling of Oak has taken place, these branches, in most cases, may be purchased for a small sum. When properly constructed, seats and trellises made of this wood are in keeping with the character of a garden; but it requires considerable experience to utilise satisfactorily these crooked sticks. The wood, too, is not very durable. Being so near the top of the tree, the branches are mostly sap wood, and when exposed to all weathers soon begin to decay. In the case of trellises this is not such a drawback, as a little decaying wood, provided there is strength enough to carry the weight, does not matter much, as it is usually hidden by climbing plants. With regard to seats, there is a want of comfort in them when made of Oak branches, and to meet this difficulty, I suggest that the seats be made of solid boards. I have just succeeded in making a seat, which is not out of character with its surroundings. This is of solid Oak, and consists of what, in the market, would be three-quarter-inch boards of very little value, that is, boards which contain knots. The supports of the seat consist of rough Oak posts, which are hidden by overhanging trees and shrubs. Although these Oak branches answer for making trellises, many of our common woods may also be used. For light constructions, provided the posts are of lasting material, the trellis itself may be made of any of the Firs which have a recognised timber value. Cut into strips of the required dimensions, even Poplar may be worked in to advantage. Considering the ease with which such things may be made, it is rather surprising that they are not more common, as, by the use of quick-growing plants, unsightly objects are so effectively covered; when obtainable, Yew is an admirable wood for such purposes. For out-of-the-way positions, where the trellis would be more of the character of a fence, slabs which come off in squaring up the various kinds of home-grown timber sometimes answer well. —D. J. YEO.
